ABSTRACT

Increasingly, school services are being guided by a problem solving approach and are evaluated by the achievement of positive outcomes. This shift is explored here in 96 chapters and 11 appendices. The volume provides a comprehensive reference relating contemporary research and thought to quality professional services. Part 1, "Professional Issues," has sections on the profession and professional supervision and leadership. Topics include ethics, legal issues, governmental relationships, and maintaining professional effectiveness. Part 2, "Focus on Systems," is divided into sections on supporting system functioning, and system level interventions. Some broad-based educational interventions are also included. Part 3, "Focus on Individualized Services," contains 55 chapters, grouped under "[The] Problem Solving Approach," "Assessment Domains for Intervention Planning," "Student Interventions," and "Specific Populations." Topics include progress monitoring, designing interventions, and measuring intervention effectiveness, as well as specific interventions. Part 4 (appendices) provides ethical guidelines, standards, position statements, state certification and licensing standards, a listing of training programs, and lists of medications used to treat children and adolescents. Each chapter contains a list of citations and at least five suggested readings. (EMK)

The content of this document reflects the ideas and positions of the authors. The responsibility lies solely with the authors and does not necessarily reflect the position or ideas of the National Association of School Psychologists.

Preface

Best Practices in School Psychology–III, like the two preceding editions published by NASP, is designed to provide a comprehensive reference for school psychologists with contemporary research and perspectives related to quality professional services. The third edition establishes a theme that is reflected in most of the chapters, emphasizing a problem-solving approach to professional practice.

A problem-solving orientation is distinguished by its purpose: to improve student performance and enhance educational success in a demonstrable manner. Problem solving is a systematic process that includes the assessment of children and their environments, identification of needs, development and implementation of supports to meet needs, and the monitoring and evaluation of outcomes. This orientation permits any theoretical approach in the design of interventions, but uses improved student performance and educational functioning as a criterion for measuring success. This commitment to improving students' performance and well-being is in harmony with NASP's mission of serving the mental health and educational interest of all children and youth.

As an aid to the reader, the book is divided into four parts with chapters clustered around identified concepts. Part 1 establishes a professional focus. Chapters in this section are related to enhancing professional services with topics ranging from the shifting paradigm in school psychology to mainstay themes within a profession such as ethics, legal issues, governmental relationships, and maintaining professional effectiveness. These chapters present content that potentially influences all other professional services. Part 2 presents a systems focus. System approaches include orientations related to collaboration and adopting prevention programs. Also in this section are systems used by school psychologists in supporting broad based educational interventions such as peer tutoring and school discipline. Part 3 considers individualized services for students, families, and schools. Not surprisingly, this is the bulk of the book. The chapters include topics related to problem solving such as progress monitoring, designing interventions, measuring intervention effectiveness, as well as assessment approaches and concepts for working with special populations. Part 4 provides a set of appendices that will be a useful professional reference including NASP ethics, standards and position statements, state certification and licensing standards, a listing of training programs across the country, as well as medications commonly used to treat children and adolescents.

Also as an aid to the reader, most chapters follow a common framework of headings. Each chapter, in addition to a list of citations from the professional literature, also includes an annotated bibliography with up to five additional readings to extend one's learning related to the chapter topic.

We hope that this organizational structure and the content of this publication will assist the profession in advancing the quality of services to educational systems, students, parents, and families. That is the intent and spirit of this publication. It is through your individual efforts that the profession collectively advances and we hope this resource will be useful in that endeavor.

Acknowledgments

Best Practices in School Psychology–III is an ambitious project that has been touched by many people. We would like to take this space to acknowledge them.

First, acknowledgments go to the cadré of reviewers who read draft chapters, provided valued feedback to authors, and shared their perspectives of the topics. Reviewers for this book include:

Much of the editorial work of tracking draft changes, final manuscripts, copyedited versions of final manuscripts, and galleys, were done by very capable Miami University graduate students in school psychology: Kelli Kazmier, Crista Chenoweth, Holly Heaviland, Cara Eichenlaub, and Kristie Dietrich.

The support of the NASP Publications Board is appreciated and Leslie Hale is to be particularly commended for providing support through the proposal to printing process.

Thanks are certainly due to Susan Gorin, NASP Executive Director, for ably clearing paths which allowed for efficient completion of this ambitious project. As usual, Rosemary O'Donnell provided inordinately competent ombudspersonship for the myriad details and problems associated with getting this task completed. NASP publications fulfillment guru, Betty Sommerville, deserves the vintner's recognition award for assuring that no book will be served before its time.

Special recognition to Paul Mendez, NASP Director for Publications, who has ably shepherded this project on the production end and he deserves credit for the final look and feel of the book. His even temper and good humor is always valued.

Kudos must also be extended to Mary Fitzhimmons and Lawrence Moran, copyeditors extraordinary. Their timeliness, incisiveness, and commitment to this project is appreciated.

All the typesetting and page layout for this book, and previous editions of this book, have been done by a remarkably energetic and efficient Judy Fulwider. Considerable, if not most, of the credit is extended to her for the timely completion of this publication.

The "anything is possible if you don't worry who gets the credit" award goes to Bonnie Thomas who did much of the detailed proofing of galleys, corrected galleys, and a thousand other details in the final preparation of this gargantuan manuscript. She has perused many words.

Acknowledgment is also extended to Doris Bergen (Chair, Department of Educational Psychology, Miami University) and Jeanne Hagen (Chief, Bureau of Special Education, Iowa Department of Public Instruction), for fostering a professional environment supportive of the editorial involvement necessary for this book's completion.

On a personal note, most heartfelt appreciation goes to the continued support received from Bonnie and Sue.

School Psychology Paradigm Shift

Daniel J. Reschly
Iowa State University

James E. Ysseldyke
University of Minnesota

In this third edition of one of the most successful volumes in school psychology, the shifting paradigm toward services guided by problem solving and evaluated by the achievement of positive outcomes is increasingly apparent. In contrast to the first two editions, the authors of nearly every chapter treat problem solving as the foundation for school psychological services with an outcomes criterion used as the basis for determining the success of problem-solving efforts. In this introduction, we describe and contrast different paradigms for the design and delivery of school psychological services, analyze problems in the traditional delivery system, and review major policy and reform statements. This introduction concludes with a discussion of the knowledge base, underlying principles, and strategies that form the basis for psychological services that emphasize problem-solving and outcomes criteria.

SCHOOL PSYCHOLOGY AND CRONBACH'S TWO DISCIPLINES

In 1957 Cronbach suggested that a merger of the two disciplines of scientific psychology would produce maximum benefits to consumers. The two disciplines, correlational and experimental, were described as differing in terms of (a) philosophical assumptions, (b) research methodology, (c) key variables and causal inferences, and (d) methods of promoting human welfare.

Correlational Discipline

The correlational discipline emphasizes assessment of the natural variations among people in cognitive, physical, and social-emotional domains. These variations are then related to actual performance in academic or employment settings. If there are significant relationships (correlations) between these natural variations and performance, increased efficiency in the use of resources and enhanced overall performance can be produced by differential selection or placement. The correlational discipline attempts to advance human welfare by selecting the best qualified persons for different careers, training programs, or instructional procedures. Cronbach suggested that the correlational tradition was more consistent with political conservatism in that the individual differences are typically seen as relatively immutable to change and the main outcome is to fit persons to existing programs.

Experimental Discipline

In contrast, the experimental discipline was seen as more liberal politically because the fundamental aim is to create higher levels of performance through, first, discovering the best interventions and then, second, disseminating and implementing the best interventions. Different treatments or interventions are carefully contrasted so that causal statements can be made about which had the highest average effects for groups of participants or, in single subject designs, for individuals. Careful control of experimental conditions is extremely important so that valid comparisons can be made between experimental conditions (i.e., treatments).

The fundamental differences between the two disciplines becomes more apparent in considering what each does with individual differences. The experimentalist attempts to create variations among persons receiving different treatments and to minimize variations among persons receiving the same treatments. Variation among persons receiving the same treatment is error, something to be controlled to the greatest extent possible. Experiments are rarely entirely successful. Some degree of variation among persons receiving the same treatment is virtually inevitable.

These more or less "natural" variations among persons — the error variance for the experimentalist — are the fundamental phenomena studied in the correlation discipline. It is this natural variation that makes differential prediction possible. Nonsignificant or attenuated prediction accuracy results from the absence of variations among persons or artificially reduced variations. Interestingly, variations among persons or individual differences are fundamental to both disciplines; however, the predictor variables in the correlation tradition contribute to the error terms in the experimental discipline. One science attempts to produce differences while the other attempts to predict performance from existing individual differences and to select more appropriate placements. In many ways the traditional and modern trends in school psychology parallel the approaches in the two disciplines.

Aptitude by Treatment Interactions

Use of aptitude by treatment interactions (ATI) was seen by Cronbach (1957) as the means to use the strengths of each of the two disciplines to maximize human welfare: "For any potential problem, there is some best group of treatments to use and some best allocation of persons to treatments" (p. 680). The ATI approach would involve study of (a) differences among treatments, (b) aptitude differences among persons, *and* (c) the interaction of aptitudes and treatments. Based on the interactions, individuals would be assigned to treatments producing the best results. The educational application suggested by Cronbach, greater emphasis on individual prescriptions, was the basis for much of school psychology over the past two decades: "We should *design* treatments, not to fit the average person, but to fit groups of students with particular aptitude patterns. ... We should seek out the aptitudes which correspond to [interact with] modifiable aspects of the treatment" (Cronbach, 1957, p. 681).

ATI is one of the most attractive ideas in all of basic and applied psychology (Arter & Jenkins, 1977, 1979; Ysseldyke, 1973). It is an idea that "should" work in the laboratory and in practice. The idea of matching treatment to naturally occurring characteristics of the person makes inherently good sense; clearly, it is consistent with our humanistic commitments of individualizing instruction and psychological treatments in order to maximize opportunities. ATI is especially attractive in school psychology where most of the work traditionally has been with individual children referred for learning and behavior problems. However, what "should" work, what is inherently appealing, is not always a sound basis for practice. Such is the case with the efforts to use ATI as the foundation for applied psychology.

ATI Failure and Short-Run Empiricism

In less than two decades, Cronbach's frustration with ATI as a basis for applied psychology was palpable in another *American Psychologist* article, "Once we attend to interactions, we enter a hall of mirrors that extends to infinity" (Cronbach, 1975, p. 119). In the ensuing years between 1957 and 1975, Cronbach and colleagues conducted many studies in which attempts were made to identify interactions of aptitudes and treatments. Unfortunately, the hypothesized interactions often did not occur, were extremely weak when they did appear, and were entangled in intractable and hopelessly complex higher order interactions that were virtually impossible to study in laboratory settings, let alone use in practical situations. Furthermore, potent interaction effects, when they did exist, were for prior achievement or skill levels within the domain(s) of behavior that was/were the dependent variable(s) in the ATI experiments. Indeed, level of prior knowledge or skills is an important variable in subsequent learning or performance; however, the effect of prior knowledge was not the kind of aptitude envisioned in Cronbach's grand design or in the school psychology applications of ATI.

In the 1975 article Cronbach abandoned ATI as the basis for applied psychology. The strategy he suggested to replace ATI was remarkably similar to the outcomes criteria and problem-solving strategies that will be discussed in more detail later in this chapter and in many of the chapters that follow. In place of ATI, Cronbach suggested context-specific evaluation and short-run empiricism, "One monitors responses to the treatment and adjusts it" (p. 126). Two realistic goals were proposed by Cronbach for applied psychology, "One reasonable aspiration is to assess local events accurately, to improve short-run control. The other reasonable aspiration is to develop explanatory concepts, concepts that will help people use their heads" (1975, p. 126). The use of short-run empiricism (problem-solving) and the selection of behavior change or instructional design principles from the available literature (selecting explanatory concepts and using our heads) is the contemporary application of Cronbach's suggestions for moving beyond the rigidity and insufficiency of the two disciplines of scientific psychology.

School Psychology Applications

Parallels to Cronbach's two disciplines in traditional and modern school psychology are easily identified. Although experimental trends were apparent in the earliest roots of school psychology (Sandoval, 1993), most of school psychology's history has been devoted to practice consistent with the correlational and ATI bases for practice (Ysseldyke, 1973). The relatively infrequent use, until recently, of single-subject designs and behavioral interventions represent the clearest applications of the experimental discipline.

The correlational parallel occurs with traditional placement services in which referred children are assessed to determine if they meet the criteria for classification as disabled. Children with low scores on measures of current intellectual functioning and academic achievement, or large discrepancies between the scores on intellectual and achievement measures, are often placed in different educational programs for part or all of their school day. The differential placement is seen as necessary to allow children to benefit educationally because the general education program is inappropriate to their naturally occurring aptitudes, a classic application of the correlational discipline described by Cronbach in 1957. The earliest roots of school psychology (Fagan, 1992; Fagan & Wise, 1994) and a substantial proportion of current practice involves assessment of children's aptitudes and achievement as the basis for placement decisions. This application of the correlational science is valid to the degree that the placements are different and beneficial for individuals, groups, or systems, an issue to which we will return in a subsequent section.

UNRESOLVED PROBLEMS IN CURRENT PRACTICE

Concerns about and alternatives to the traditional practice of school psychology have become increasingly prominent over the last 20 years. These problems and suggested solutions closely parallel the different applications of the two disciplines of scientific psychology, the ATI movement, and Cronbach's endorsement of practice that is informed by theory and research and guided by a methodology of short-run empiricism.

Nature of Current Practice

Survey studies of the practice of school psychology yield consistent results (Reschly & Wilson, 1995; Smith, 1984). School psychologists devote about two-thirds of their time to activities related to special education classification and placement, with slightly over half of the time devoted to individual assessment activities, usually with standardized measures of ability and achievement. These surveys also indicate that current practitioners prefer to spend more time in direct and indirect activities related to interventions such as individual counseling and problem-solving consultation. The value of the current time allocations depends heavily on the benefits to students associated with classification as disabled and placement in special education programs. Do differential diagnoses such as mild mental retardation (MMR) or specific learning disability (SLD) lead to different treatments, and are those treatments differentially effective depending on the student's diagnosis?

Effectiveness of Special Education

The single greatest problem with current practice is the uncertain benefits of special education classification and program placement for students with mild disabilities (mild disabilities constitute approximately 85% to 90% of the students in special education programs; Algozzine & Korinek, 1985; Reschly, 1987). This is an old problem (e.g., Dunn, 1968). Yet recent evidence provides little confidence in the utility of current diagnostic categories or in treatments based on aptitudes (Kavale, 1990).

In Table 1 the outcomes of program placement and aptitude-based treatments are summarized based on Kavale's 1990 review. The first two rows contain the average effect of being classified as MMR or SLD and placed in special education. These meta-analyses are consistent with the interpretation that classification as MMR or SLD and special education placement produces negligible effects in the former case and weak effects in the latter case. Traditional aptitude-based treatments also fare poorly in the meta-analyses (see the third and fourth rows in Table 1). Matching instructional methodology to visually based or auditorially based aptitudes has no positive effects. The disappointing outcomes associated with traditional diagnoses such as MMR and SLD and with matching intervention methodology to aptitudes is part of the "push" toward system reform.

Nonfunctional and Stigmatizing Labels

In most states, a specific disability must be designated as part of a classification and placement process whereby children and youth with learning and behavior problems receive special education and related services. School psychologists usually are the key players in determining which disability is most appropriate for a specific student. The critical question is, "Do the mild disability categories make any difference to treatment?" (Reschly, 1987, 1988; Ysseldyke, 1973, 1988; Ysseldyke, Algozzine, Regan, & McGue, 1981; Ysseldyke, Algozzine, Shinn, & McGue, 1982; Ysseldyke, Thurlow, Christenson, & Weiss, 1987).

Substantial evidence indicates that the same treatment goals and teaching strategies are adopted regardless of the category of mild disability (Reynolds & Lakin, 1987). For example, the top IEP goals typically are reading, then math, then written expression regardless of whether the disability is MMR, SLD, or behavior disorder (BD), and the same teaching strategies are used regardless of disability category. Furthermore, programs for low achieving students (e.g., Chapter I) and special education for students with mild disabilities are highly similar in terms of the needs of the students served and the intervention methodology used. Despite these similarities, markedly different levels of financial support are provided in special education and Chapter I, often on the basis of a few points on a test or a pair of tests. Some students are called disabled (and lots more money spent on their education) while others remain in regular education with little assistance. Do these distinctions make sense? It is difficult to justify the

TABLE 1
Summary of Effect Sizes in Meta-Analyses of Placements and Interventions

Placement/Intervention	**Effect Size[a]**
MMR Diagnosis/ Special Education Placement	-.14
SLD Diagnosis/Special Education Placement	.29
Modality Matched Instruction (Auditory Strength)	.03
Modality Matched Instruction (Visual Strength)	.04
Behavior Modification/Behavior Therapy (Social Behavior Goals)	.93
Curriculum-Based Progress Monitoring with Formative Evaluation	.70
Curriculum-Based Progress Monitoring with Formative Evaluation and Systematic Use of Reinforcement	1.00

Note. The results in this table are abstracted from results reported by Fuchs and Fuchs (1986) and Kavale (1990). Interested readers are referred to those sources for more information.

[a] Effect size expresses in standard deviation units the average results of interventions, placements, or treatments from many studies.

labeling process if program benefits are not clearly documented (Gallagher, 1972) and if differential treatment is not related to the category assigned (Cromwell, Blashfield, & Strauss, 1975; Heller, Holtzman, & Messick, 1982). System reform efforts often involve noncategorical special education, with less emphasis on finding the right category, or differential diagnosis among disabilities, and more emphasis on determination of programming needs and design of interventions (Reynolds & Lakin, 1987; Ysseldyke, 1988).

The Special Problem of Specific Learning Disabilities

Nearly every system reform discussion focuses more attention on SLD than any other area. Why? Because of the "Willie Sutton" reason. Sutton, a notorious bank robber in the 1930s, was asked, "Why do you rob banks?" His reply was, "That's where the money is." Similarly, the reason for the focus on SLD is that although SLD is only 1 of 13 categories of disability recognized in federal legislation, slightly over half of all students with disabilities are classified as SLD.

Although there are many tantalizing findings in the LD research, few generalizations can be made beyond the observation that students with LD have low achievement, most often in reading. The same conclusion applies to students in Chapter I programs. Notably absent in the LD research and practice is evidence for validated differential treatment based on the LD diagnosis or the identification of reliable subtypes of LD for whom matching treatment to subtype produces better outcomes (Epps, Ysseldyke, & McGue, 1984; Shinn, Tindal, Spira, & Marston, 1987; Shinn, Ysseldyke, Deno, & Tindal, 1986; Sleeter, 1986; Ysseldyke & Algozzine, 1983; Ysseldyke, Algozzine, & Epps, 1983; Ysseldyke, Algozzine et al., 1982; Ysseldyke, Thurlow, Graden, Wesson, Algozzine, & Deno, 1983).

Treatment Validity of Assessment Procedures

In Table 2 the most frequently used assessment procedures by school psychologists in a 1991–1992 survey are listed. Two rather dramatic conclusions are apparent from examination of this list. First, many of the instruments have mediocre to poor technical characteristics (Christenson & Ysseldyke, 1989; Reschly, 1980; Salvia & Ysseldyke, 1978, 1995; Witt, 1986; Ysseldyke, Algozzine, Regan, & Potter, 1980; Ysseldyke & Thurlow, 1984). Second, the instruments with strong technical characteristics (Wechsler Scales and Woodcock-Johnson Achievement) have relatively little application to the determination of specific treatment needs or to monitoring and evaluating the effects of treatments. As noted in a *Buros Mental Measurements Yearbook* review, the Wechsler Scales have excellent technical characteristics related to determining relative standing in a normative group, information useful for classification but largely irrelevant to treatment: "In short, the WISC-R lacks treatment validity in that its use does not enhance remedial interventions for children who show specific academic skill deficiencies" (Witt & Gresham, 1985, p. 1717).

Aptitude by Treatment Approaches

The original ATI applications in school psychology and special education involved *training* weak areas in perceptual-motor or psycholinguistic domains, or *matching* instructional methodology to strong areas in these domains (Mann, 1979). By the early 1980s these approaches generally were viewed as ineffective (Arter & Jenkins, 1977, 1979; Hammill & Larsen, 1974, 1978; Kavale, 1981; Kavale & Mattson,

TABLE 2
School Psychologists' Self-Report of Assessment Instruments' Use Per Month

1983; Ysseldyke, 1973; Ysseldyke & Mirkin, 1982). Despite this negative evidence and the more general complications of ATI research (Cronbach, 1975), the practice of attempting to match instruction to aptitude strengths continues to be prominent in some recommendations for school psychology practice. Recent aptitude constructs used in the matching process involve cognitive processing strengths such as successive or simultaneous processing or neuropsychologically intact areas (Hartlage & Reynolds, 1981; Hartlage & Telzrow, 1986; Kaufman, Goldstein, & Kaufman, 1984; Kaufman & Kaufman, 1983; Reynolds, 1981, 1986, 1992). These aptitude-by-treatment constructs have been no more successful than their information-processing-modality predecessors (Ayers & Cooley, 1986; Ayers, Cooley, & Severson, 1988; Good, Vollmer, Creek, Katz, & Chowdhri, 1993). Indeed, the major barrier to the use of these more recent aptitude constructs in school psychology is the near total absence of treatment outcome results wherein the aptitudes are assessed, intervention methodology is matched and mismatched to these aptitudes, interventions are implemented, and results are carefully examined (Teeter, 1987, 1989). Whether aptitude is conceptualized as cognitive processes, information processing modalities, or intact neurological areas, Cronbach's (1975) characterization of ATI is still accurate, "Once we attend to interactions, we enter a hall of mirrors that extends to infinity" (p. 119).

Disjointed Incrementalism

Disjointed incrementalism refers to the increasingly separate general and special education systems and the myriad of special programs with separate funding streams and eligibility criteria but similar goals and clientele (Reynolds, Wang, & Walberg, 1987). The consequences of the current organization of services is inefficient use of funds, uncoordinated programs, curricular discontinuity, and limited generalization of effects across settings. System reform plans typically attempt to combine various services and achieve better integration of general and special education programs.

Quality of Interventions

One of the greatest concerns is the quality of current interventions (Flugum & Reschly, 1994; Gresham, 1989; Gresham, Gansle, Noell, Cohen, & Rosenblum, 1993). Basic intervention principles often are not implemented in IEPs, special education programs, and prereferral interventions, and these interventions typically are not evaluated using individualized, treatment sensitive measures. Absence of high quality interventions coupled with poor evaluation of individual progress may alone account for the undocumented benefits of special education.

Disproportionate Minority Placement

Disproportionate minority placement may be the quintessential special education issue in the last quarter of this century, an issue that has not gone away (U.S. Department of Education, 1992). Most analyses of this issue have focused on testing and placement processes. Such analyses answer some questions but miss the main issue: specifically, the effectiveness of special education programs for students with mild disabilities and the development of effective alternatives that meet the enormous needs of economically disadvantaged students who are now overrepresented in special education (Reschly, Kicklighter, & McKee, 1988a, 1988b).

Consider these facts. More money is spent on the student's education in special education. There is a lower student–teacher ratio. The program is individualized and the teacher typically has additional training. Yet plaintiffs representing minority students overrepresented in special education programs clearly did not see special education as a good bargain. Why? Was it because of overrepresentation? That is a simple answer, but it is as wrong as it is simple! Consider other programs such as Head Start and Chapter I. More overrepresentation exists in those programs than in special education and those programs involve many more students. But there has been scant concern raised about overrepresentation in these areas.

If overrepresentation is not the answer, then what explains the motivation of minority plaintiffs? Scrutiny of the evidence presented by plaintiffs, judicial decisions, and other writings by plaintiffs provides clear evidence that overrepresentation was a symptom associated with critical assumptions about classification as disabled and placement in special education. Plaintiffs asserted that classification was stigmatizing and associated with few if any benefits because of the ineffectiveness of special education programs and that biases in referral, assessment, and decision making caused the overrepresentation. Although some of these assumptions are incorrect, or at least arguable, defending the effectiveness of special education was the most difficult challenge for the defendant school districts and state departments of education in the overrepresentation litigation (Reschly et al., 1988a, 1988b).

SYSTEM REFORM

Attention to the most effective ways that school psychologists can promote the mental health and educational interests of children and youth has been prominent in the modern school psychology literature (e.g., Cutts, 1955; Gray, 1963). The current Zeitgeist in school psychology began about 15 years ago with two national conferences on the future of psychology in the schools (Ysseldyke, 1982). Interested readers are referred to several papers from these conferences that appeared in special issues of the *School Psychology Review* (see especially Grimes, 1981; Trachtman, 1981).

One of the most influential documents developed soon after the conferences was *School Psychology: A Blueprint for Training and Practice* (Ysseldyke, Reynolds, & Weinberg, 1984). Key recommendations in *Blueprint* have been incorporated in other policy statements and reform documents. The most important themes in *Blueprint* were:

1. Eliminating the categorical classification of students with mild disabilities and replacing those classification and placement practices with interventions in natural settings guided by problem-solving procedures with curriculum-based and behavioral assessment measures.

2. Greater emphasis on systems to manage challenging behaviors rather than individual, within-child studies to identify disorders.

3. Greater emphasis on increasing the capabilities of general education to provide appropriate programs for children with learning and behavior problems rather than diagnosis of disabilities and placement outside of general education.

4. Transformation of psychologists' roles from individual diagnoses of disabilities to support of classroom instruction in academic and social behaviors through problem-solving consultation and direct interventions.

5. Closer working relationships among parents and teachers to capitalize on opportunities to develop interventions designed and implemented simultaneously by parents and school officials.

In 1985 the policy statement, "Advocacy for Appropriate Educational Services for All Children" was passed unanimously by the Executive Board and Delegate Assembly of the National Association of School Psychologists (NASP). One year later that body unanimously adopted the policy statement, "Rights Without Labels." Both statements rejected the traditional methods of classifying children as disabled in order to provide services and strongly advocated development of systems that provided services and supports needed by children and youth without labeling them "disabled." Both statements proposed establishment of experimental system change programs that would investigate ways to provide services without labeling and, at the same time, maintain rigorous protection of the rights of parents and students.

In the late 1980s the knowledge base for school psychologists' roles in reformed systems was significantly improved by the publication of an alternative delivery systems monograph (Graden, Zins, & Curtis, 1988), followed a few years later by a monograph on interventions (Stoner, Shinn, & Walker, 1991). Parallel to these developments was the special education research synthesis project culminating in a two-volume compendium of research reviews (Wang, Reynolds, & Walberg, 1987, 1988) and a synthesis of these reviews (Wang, Reynolds, & Walberg, 1990). Several of the major system reform recommendations in the synthesis were reminiscent of the classification project led by Hobbs (1975). Common to both was the concern about the usefulness of traditional disability designations such as SLD, MMR, and BD. Common to both was the commitment to providing necessary instructional and support services to children and youth with learning and behavior problems in natural settings to the greatest extent possible and to better implementation of the available knowledge base regarding instructional design and behavior change principles.

A recent policy statement on assessment and eligibility in special education goes still further in delineating the system changes needed to capitalize optimally on the current knowledge base regarding assessment and intervention (NASP-NASDSE-OSEP, 1994). Again, the first step emphasized is to change the categorical classification system and to fund services and supports needed by children and youth without disability categories. This statement establishes the context for applying the knowledge base on system reform (see Graden et al., 1988) and principles of instructional design and behavior change (see Stoner et al., 1991) through describing a comprehensive problem-solving approach that would be used to determine eligibility for services, to organize and provide those services, to monitor progress and change programs as needed, and to evaluate outcomes.

Summary

We are *pushed* by problems in the current system to consider alternatives to conventional referral, assessment, classification, and placement practices. These pushes provide the motivation to consider alternatives. Policy statements over the past decade have described the necessary changes in the delivery system that will permit the delivery of psychological services more closely related to the needs of children, youth, and families. Although the way to a reformed and more effective practice of school psychology has been charted in a general way, descriptions are still needed of specific bodies of knowledge, assessment skills, and intervention competencies.

ADVANCES IN ASSESSMENT AND INTERVENTION

We are *pulled* to delivery system alternatives by advances in assessment and intervention techniques that have the promise to substantially improve the outcomes of special education. Implementation of these alternatives has the potential for creating a revolution in how school psychology is practiced in the United States (Reschly, 1988; Ysseldyke, Reynolds, & Weinberg, 1984).

Assessment has been, and will continue to be, a salient activity in the roles of school psychologists; however, vast changes will occur with system reform in assessment purposes, techniques, and outcomes (Christenson & Ysseldyke, 1989; Reschly, 1980, 1986; Ysseldyke, 1984; Ysseldyke & Christenson, 1988; Ysseldyke & Thurlow, 1984). Purposes will focus more on interventions, specifically, what can be changed in environments to produce improved learning and behavior. In the first edition of *Assessment in Special and Remedial Education*, Salvia and Ysseldyke (1978) described five purposes for assessing students: screening, classification, instructional planning, pupil evaluation, and program evaluation. Fifteen years later developments in assessment practices required expansion of that characterization to recognition of 13 kinds of decisions made with assessment information (Salvia & Ysseldyke, 1995). These 13 decisions are organized into four areas: prereferral classroom-based decisions, entitlement decisions, postentitlement classroom decisions, and accountability/outcomes decisions (see Figure 1). Assessment practices are expanding; they are moving to earlier stages of intervention and to new kinds of decisions.

Techniques will increasingly involve gathering information in natural environments with direct measures of behaviors that can be used frequently as interventions are implemented. These measures will be used to define problems, to establish intervention goals, to monitor progress, and to evaluate outcomes. These measures also will be used as the basis for classification of students as eligible for more intensive instructional or social/emotional intervention programs, including special education (Deno, 1985; Germann & Tindal, 1985; Marston & Magnusson, 1988; Reschly, 1986; Shapiro, 1989; Shapiro & Kratochwill, 1988; Shinn, 1989; Shinn & Marston, 1985; Shinn, Tindal, & Stein, 1988).

Outcomes Orientation

A major shift to a focus on outcomes rather than intervention inputs or processes is apparent in the reform literature. An outcomes orientation has been applied to analyses of overrepresentation of minority students in special education (Reschly, 1979; Reschly & Tilly, 1993). Greater attention to documentation of outcomes is pervasive in general and special education (Ysseldyke, Thurlow, & Bruininks, 1992). The push to document the outcomes of education has its roots in concern by business and community leaders about the relatively low-level skills exhibited by the people they hire and in concern about the relatively low standing of American students in international comparisons. It used to be the case that directors of special education described their special education programs by talking about numbers of students, categories of students, settings in which they were educated (e.g., resource rooms), and kinds of teachers and instructional programs. Now the scene is shifting and administrators are being asked about the extent to which students reach outcomes (read, write, and cipher).

State education agencies are specifying standards, goals, or outcomes students are to achieve and are devising ways to measure attainment of out-

comes. The national education goals panel is reporting on the extent to which students are achieving national education goals. Some states include students with disabilities in their outcomes assessment practices, others exclude these students. Approximately 40% to 50% of school-age students with disabilities are excluded from some of the most prominent national educational-data-collection programs (McGrew, Thurlow, & Spiegel, 1993). School psychologists are increasingly involved in the business of helping specify indicators and measures of outcomes that stakeholders believe are important. As they do so, a number of conceptual and technical issues arise (Thurlow & Ysseldyke, 1994).

Problem-Solving Orientation

Several problem-solving approaches have appeared in the literature, with slight variations related to intended population or type of problem (Bergan, 1977; Bergan & Kratochwill, 1990; Gutkin & Curtis, 1990; Knoff & Batsche, 1991; Rosenfield, 1987). All have common features involving problem definition, direct measures of behaviors, design of interventions, monitoring of progress with intervention revisions as necessary, and outcomes evaluation. All are more consistent with the experimental tradition in psychology as well as the short-run empiricism described by Cronbach (1975) as a promising replacement for interventions guided by aptitude-by-treatment interactions.

Problem solving is an essential component of implementing advances in assessment and interventions. We caution against superficial versions of problem solving, particularly those that do not involve precisely defined problems, direct measures of behavior, preintervention data collection, intentional application of instructional design and behavioral change principles, frequent progress monitoring with program changes as needed, and evaluation of outcomes through comparisons to initial levels of performance. As Fuchs and Fuchs (1992) noted, "feel good" consultation is likely to make the participants (e.g., psychologist and teacher) feel good, with little benefit to students.

Problem solving provides the overall structure for an alternative delivery system. Different levels of problem solving are illustrated in Figure 2, which represents the system developed by the Heartland Area Education Agency in Iowa. The four levels of problem solving involve different degrees of intensity and different levels of special education and support services involvement. The first two levels are conceived as occurring entirely within general education with occasional involvement of related services providers such as psychologists. Level III problem solving, involving related services personnel, is a rigorous, data-driven, intervention effort that must meet exacting standards for parent involvement, problem definition, systematic data collection, problem analysis, goal, intervention plan development, intervention

plan implementation, progress monitoring, and decision making. Detailed standards have been developed for each of these problem-solving components (Bureau of Special Education, 1994). Interventions meeting these quality indices must be implemented for a reasonable period of time and found to be insufficient according to progress monitoring data before Level IV problem solving is initiated.

In Level IV problem solving, classification of the student as needing special education may be considered based on documentation of (a) substantial discrepancies from average levels of classroom performance that are not resolved to a sufficient degree by high quality interventions in general education or (b) behavioral discrepancies that require programming elements or instructional intensity beyond the resources that reasonably can be provided in general education. This system depends heavily on problem solving, curriculum-based and behavioral assessment, and high quality interventions. A critical eligibility criterion is resistance to intervention (Gresham, 1991), with rigorous standards established for quality of interventions. Further discussion of each of these areas appears in other chapters in this volume.

Assessment Technology and Decision Making

Significant advances in assessment technology permit greater emphasis on measures functionally related to interventions. Most of these advances can be classified as behavioral assessment procedures (Shapiro & Kratochwill, 1988). The knowledge base for practice has improved substantially with the development of curriculum-based assessment and curriculum-based measurement (Deno, 1985; Howell, Fox, & Morehead, 1993; Shapiro, 1989; Shinn, 1989). Advances in the assessment of instructional environments provides further technological support to academic and behavioral interventions (Christenson, Ysseldyke, & Thurlow, 1989; Ysseldyke & Christenson, 1987a, 1987b, 1993; Ysseldyke, Christenson, & Kovaleski, 1994; Ysseldyke & Marston, 1990). Parallel advances in behavioral assessment of social and emotional phenomena have led to equally substantial improvements in practice in these areas (Alessi & Kaye, 1983; Shapiro & Kratochwill, 1988). Technologically sophisticated assessment methods, Ecobehavioral Assessment Systems Software (EBASS; Greenwood, Carta, Kamps, Terry, & Delquadri, 1994) have been developed to aid in the detailed collection of observational data in classrooms.

The assessment technology to support practice guided by an outcomes criterion is now available for the first time in the history of school psychology. Behavioral assessment measures also can be used in decisions about eligibility for various special programs and in decisions about placement (Gresham, 1985, 1991; Shinn, 1988; Shinn et al., 1988). It appears that virtually the same students will be identified as needing specialized instruction and social-emotional interventions using behavioral assessment procedures; however, the behavioral assessment procedures yield information useful for intervention planning and evaluation as well as eligibility determination.

Instructional Design

Behavior assessment and instructional analysis are inextricably related in functional assessment of academic behaviors. The marriage of instructional design principles (e.g., Englemann & Carnine, 1982) with behavioral intervention technologies have produced impressive outcomes for students (Becker & Carnine, 1980; Kavale, 1990). As noted in the last three rows of Table 1, the effects of interventions based on behavior therapy principles, combined with progress monitoring and changes in programming based on results (Fuchs & Fuchs, 1986; recall Cronbach's short-run empiricism), produce strong effects according to the meta-analysis evidence. Use of this knowledge base produces results markedly superior to traditional special education programs or instruction based on matching teaching methods to presumed strengths in cognitive style, information processing, or neuropsychological status. Much of system reform is driven by the desire to implement more effective interventions.

Behavior Change

Behavior change principles are well established (Stoner et al., 1991; Sulzer-Azaroff & Mayer, 1991). In addition, characteristics of effective schools and effective teaching are well represented in the school psychology literature (e.g., Bickel, 1990). There is a solid knowledge base for assessment and intervention; however, the remedial programs for most children and youth do not apply all, or even most, of this knowledge base.

Summary

One of the main themes in system reform is improved application of the available knowledge on assessment, instruction, learning, and behavior change. Improved application of this knowledge base will be facilitated by the movement toward noncategorical classification and integration of diverse programs intended to serve children and youth. Reductions in the amount of time devoted to standardized testing to determine eligibility will permit greater opportunities for school psychologists to be involved in new roles related to functional assessment, interventions, and evaluation of student progress.

POLITICAL VALIDITY OF SYSTEM REFORM

The major statements on system reform emphasize the importance of the *process* whereby reforms are designed and implemented. The system reform statement endorsed unanimously by the NASP Delegate Assembly in March 1985 stressed, "the development and piloting of alternatives" as well as the "need to assure that no child is put at risk for loss of services while the change process is occurring" (National Association of School Psychologists, 1985). Since 1985, NASP has devoted considerable resources to critical elements of system reform including policy advocacy and continuing education of school psychologists (Cobb & Dawson, 1989; Graden et al., 1988; Stoner et al., 1991). Politically valid reforms have the critical elements of fair and equitable distribution of resources, involvement in decision making, protection of jobs, and continuing education opportunities (Jenkins, Pious, & Peterson, 1988).

Resource Allocation

System reform often involves development of different ways to fund programs. Two protections are critical. First, system reform cannot be allowed to become a way to reduce financial support of special and remedial programs for children and youth. The legitimacy of system reform requires at least stable resources. Second, alternative methods of funding programs and alternative resource allocation procedures should first be pilot tested in smaller units (e.g., a few districts, or regional units in a state) before application to the entire system.

Involvement in Decision Making

Constituents of the present system should be involved in decision making regarding the design of alternative delivery systems. Constituents should be viewed broadly, including related services professionals, special educators, general educators, parents, and children and youth. Leadership by psychologists is essential to successful system reform; indeed, the major advances in assessment and interventions on which reforms are based originated in basic and applied psychology! Ensuring that the available knowledge base is implemented is a crucial role for psychologists in system reform.

Protection of Jobs

Practitioners in the current system are asked in system reform to support significant changes that affect the way they do their jobs and the kinds of professional roles that are valued. The roles of some practitioners may change dramatically. The legitimacy of system reform depends on guaranteeing the employment of these persons, at least in the short term, and providing for them ample continuing education opportunities to acquire skills needed in the new system. Each individual should get a fair shot at continuing his or her employment in a valued role if they are willing to acquire the skills needed in the new system.

Continuing Education

Continuing education opportunities are perhaps the single most important feature of system reform. Most of us have ample continuing education needs, expressed eloquently by one of our leading scholars, "I have saved my course notes from graduate school. With the exception of statistics, everything I was taught no longer is true" (Bardon, 1981, p. 202). The advances in assessment and intervention are not well represented in all graduate school psychology programs; indeed, it is our observation that many of us who are university faculty have continuing education needs that equal and, in most cases, exceed those of typical practitioners!

Traditional school psychology training provides an essential foundation for system reform that can be used as a base in meeting our continuing education needs. The knowledge base in learning, normal and exceptional patterns of development, sensitivity to cultural differences, measurement, assessment, counseling methods, and relationship skills is unique among related services personnel and essential to successful performance of roles in new systems. To this traditional knowledge base, systematic problem solving, consultation, principles of behavior change, principles of instructional design, and functional assessment need to be added.

The design of continuing education is crucial (Reschly & Grimes, 1991). Most current continuing education can be characterized as "train and hope" because actual supervised practice with feedback in implementation of new skills is not provided. Effective continuing education that leads to persistent changes in professional services requires a multistep process, that is,

1. Awareness and knowledge acquisition.
2. Demonstration.
3. Simulated try-out with feedback.
4. Implementation in the work setting with feedback.
5. Additional training opportunities to overcome problems that emerge in implementation.
6. Support and incentives for changing roles through performance evaluation and other mechanisms.

PARADIGM SHIFTING AND LEADERSHIP BY PSYCHOLOGISTS

The paradigm shift is occurring at different rates and in varying forms throughout the United States. There are, however, few states that have not been involved in special education reform and the pace of change is anticipated to quicken in the later part of the 1990s. We acknowledge that a paradigm shift does not occur quickly or easily; indeed, many unanticipated barriers have been encountered and there are undoubtedly more to come. Despite the necessity to acknowledge significant impediments to reform, we remain optimistic about the delivery system and role changes described in this and other chapters in this volume. Our faith is based on a conviction that the delivery system and role changes are in the best interests of children, youth, and families and that application of the outcomes criterion will increasingly invigorate and strengthen the support for a paradigm shift from the correlational science of prediction and placement to an experimental science of interventions designed to maximize learning guided by short-run empiricism. This paradigm shift means making differences in, rather than predictions about, students' lives.

Best Practices in Professional Conduct: Meeting NASP's Ethical Standards

Philip B. Bowser
Roseburg (Oregon) Public Schools

OVERVIEW

Ethos, the Greek root for "ethics," refers to "the characteristics and distinguishing attitudes, habits, beliefs, etc. of an individual or of a group" (Guralnik, 1974). Over the years, the word transformed into *ethics*, the branch of philosophy that deals with conduct and character, and the concepts of right and wrong (Singer, 1993). Professional groups eventually applied the term to rules and regulations that limit the range of acceptable behavior for members of the group. There should be a central core of commonly shared beliefs applicable to all school psychologists (including graduate students, university professors, research specialists, internship/practicum supervisors, etc.), regardless of job site, and pertinent to the manner in which they conduct themselves.

This is particularly important for a profession that does not speak to consumers with a single voice about what is "best practice." Over the course of several years, teachers and parents are likely to meet school psychologists who approach problems from the behavioral, Freudian, neurological, collaborative/consultative, or systems point of view. How could service consumers recognize a school psychologist unless there was some common thread connecting the various training backgrounds?

The development of a set of ethics is a common task for a professional association. The National Association of School Psychologists described the benefits in the introduction to the *Professional Conduct Manual* (National Association of School Psychologists [NASP], 1992b):

> By virtue of joining the Association, each NASP member has agreed to act in a manner that shows respect for human dignity and assures a high quality of professional service. Although ethical behavior is an individual responsibility, it is in the interest of an association to adopt and enforce a code of ethics. If done properly, members will be guided towards appropriate behavior, and public confidence in the profession will be enhanced. Additionally, a code of ethics should provide due process procedures to protect members from potential abuse of the code. (p. 5)]

To develop this code of ethics, NASP's Ethics and Professional Conduct Committee systematically obtained recommendations from the ethics committees of state school psychology associations. Practicing school psychologists, university trainers, students, administrators, and a wide range of NASP leaders commented on the rough drafts. The NASP Delegate Assembly approved the document in 1984, making it the standard for individual NASP members and the state affiliates. Following the same tradition of working collaboratively at the grass roots level, *Principals for Professional Ethics* (hereafter *Ethics*) was revised in 1992 with the intent of representing "a national consensus regarding the professional behavior required of school psychologists in any setting (NASP, 1992a, p. 3).

The individual student or practitioner of school psychology who studies NASP's *Ethics* will find what seems to be mostly common sense advice. For example, school psychologists are told to be advocates for their students/clients, to provide only services for which they have achieved a recognized level of competency, and to refrain from sexual exploitation. This sounds easy enough in the abstract, from the comfort of one's favorite reading chair. But the "real world" is full of organizational pressures, conflicting regulations, and personal challenges that can very quickly make fuzzy and grey the sharp, black-and-white distinctions found in a book.

People expect ethical challenges to be rather rare and obviously large, such as the offer by a parent of a $50 bribe to make sure a child receives an IQ score high enough to assure entry into a talented and gifted program. In fact, opportunities to act unethically tend to be more subtle, and appear almost daily. Take, for example, the supervisor who says "We are out of funds for materials — just make a photocopy of the test protocol." Unless one had carefully studied NASP's *Ethics*, it would be rather easy to succumb to the pressure to complete work in a timely manner, to follow orders in a "good soldier" spirit. The probability of penalty is low; the probability of praise is high. By acting quickly, one might even help bring some relief to a suffering student — yet it would be a clear violation of the ethical principles.

Time magazine recently surveyed 285 therapists across the United States. Forty-six percent reported "feeling so angry with a client that you do something you regret later" and 20% reported "flirting with a client" (Therapists and Their Patients, 1993). These are people who were trained to know better, and yet the numbers are too high. Evidently the human condition is such that we need to be in a state of constant alertness for potentially unethical behavior.

The intent of this chapter is to describe for the reader several sources of guidance about appropriate professional behavior. The author will attempt to distill the basic themes, which should make it easier to recall general ethical principles. Case studies will provide a model of a problem-solving approach to the analysis of an "ethical dilemma."

BASIC CONSIDERATIONS

For each employment situation, the school psychologist will find a variety of potentially conflicting sources of advice regarding appropriate behavior. NASP, the American Psychological Association (APA), and the National Education Association (NEA) all publish principles for professional ethics, which present the particular view of the organization. These rules are binding on their respective members, and some professionals may belong to all three associations, or more. NASP, as well as other publishing firms, prints *Best Practices* books, such as this one. NASP also releases several standards documents and occasionally the NASP Delegate Assembly issues a "position statement." Most employers have an employee handbook that describes policies and procedures. Then there are state laws, federal laws, and the rules that implement them. The application of the statutes are modified by case law, and there are various attorneys and university professors who earn additional money by promoting their latest opinions. Since these were all developed independently of each other, chances are good that they will fail to agree in many areas. What to do?

For NASP members the answer is relatively simple. As noted in the *Principles for Professional Ethics* (NASP, 1992a):

> As a general rule, the Association will seek to enforce the *Ethical Principles* upon members. The *NASP Standards for the Provision of School Psychological Services* are typically not enforced, although all members are encouraged to work towards achieving the hallmarks of quality services delivery that are described therein. Similarly, "position statements" and "best practices" documents are not adjudicated. (p. 5)

(Readers are advised that NASP standards also apply to nonmembers who hold National Certification.)

Therefore, NASP's *Ethics* should be the basic reference document for NASP members. It is typical for ethics documents to provide a series of relatively general principles instead of an exhaustive list of rules. This is done to provide stability across time; general procedures are not as likely to be influenced by current fads. It also prevents individuals from claiming they cannot be charged with an ethical violation because there was not a specific item in the text that deals with a unique situation. It does place a responsibility on the individual member to study NASP's *Ethics*, reflect on the intent of the sections, and determine how those principles apply to a particular employment setting or a specific sequence of events.

Let's turn to the NASP documents now, and search for common themes running throughout. Drawing on the work of several writers, Jacob and Hartshorne (1992) found four basic motifs repeated in the scores of the helping professions.

Welfare of Client

This theme refers to respect for the dignity and human rights of the individual, including "self-determination and autonomy . . . privacy and confidentiality . . . the values of fairness and nondiscrimination" (Jacob & Hartshorne, 1992, p. 12). A quick scan of the *Ethics* finds phrases such as "This objective is pursued in ways that protect the dignity and rights of those involved" (III-A-1); "School psychologists respect all persons and are sensitive to physical, mental, emotional, political, economic, social, cultural, ethnic, racial, gender, sexual preference, and religious characteristics" (III-A-2). School psychologists are also called upon to respect the wishes of those who object to their services (III-C-3). A nondiscrimination statement can be found in III-E-3. Respect for individual integrity and individual differences is required by IV-B-1-a, specifically with regard to assessment and intervention practices. Similar sections are found in *Standards for the Provision of School Psychological Services* (NASP, 1992c; hereafter *Standards*), particularly in regard to respect for the contribution of cultural groups.

Even though one may feel proud of one's rigorous training, unique experiences, and understanding of the schooling process, this theme requires humility. Achieving the rank of school psychologist is supposed to imbue one with a greater understanding of individual differences and a profound respect for human rights. Arrogance is antithetical to the goals and purposes of the profession.

Professional Competence

Mastery of one's craft should lead to a high proportion of correct decisions. When parents or teachers ask for assistance, competent school psychologists should be able to deal with such requests in a manner that leads to improvement in their students' condition; at the very least, they should do no harm. This will require that they be certain which skills are fully developed, and which are not yet ready for presentation to the public. Supervision and continuing professional development are assumed under this theme, as is one's ability to accept total responsibility for actions taken (Jacob & Hartshorne, 1992, p. 14).

The second paragraph of the introduction to *Ethics* clearly calls for school psychologists to do no harm and to provide only competent services. Section II deals with this theme in greater detail, and a number of statements in the other sections provide some suggestions for how to "maintain the highest standard" (IV-B-1).

There may be times when agencies or individuals apply pressure to the school psychologists to reduce the quality of services in order to see more students in a shorter time. Or perhaps there is a desperate need for a particular type of service, one that some specifically trained school psychologists could provide, but the school psychologist assigned to the area lacks the competence. According to *Ethics*, and the principle of "responsible caring" (Jacob & Hartshorne, 1992, p. 14), the only course of action is to resist the pressure. One must provide only high-quality services; one must reach a recognized level of relevant training before providing a given service.

Integrity of Professional Relationships

In dealing with other professionals, this tenet implies that school psychologists are open, honest, and fair. Their actions are based on principles, not defensive emotions. School psychologists are aware of conflict of interest situations, and do not allow their special place in the school system and the community to bring them unfair advantage.

In *Ethics*, there are many references to avoiding conflicts of interest and maintaining professional relationships at the highest level. The entirety of Section III-F specifies actions for dealing with related professions. Section III-D-4 recommends: "As much as possible, the stance of the school psychologist is made known in advance to all parties to prevent misunderstandings." Perhaps the easiest way to prevent misunderstandings is to explain school psychology services *a priori*. In that way, any potential conflicts can be revealed and an agreeable solution developed before any difficulties arise.

Responsibility to Community/Society

This section recognizes school psychologists' status as citizens, and that they are not denied their rights to participate in the political process because of their training or employment. Section III-E-1 of *Ethics* cautions that political activism should not compromise one's professional effectiveness. Section III-E-2 prescribes making certain that attempts to bring about social change should be accomplished lawfully, and further requires that individual actions not be presented as representing the profession of school psychology.

Special additional responsibilities fall on those who perform research with human subjects (*Ethics* III-A-6, IV-D-1, IV-D-2; *Standards* 4.3.5.1). Individual practitioners conducting private practice also need to be especially careful to avoid providing diagnosis or therapy through public channels (*Ethics* V-B-4). Announcements and advertising are also limited to presentation in a formal, professional manner (*Ethics* V-C-1 through V-C-7). State licensing boards will undoubtedly have additional restrictions for those in private practice. These would make interesting reading for the public sector practitioner who collaborates with the private sector.

These common themes provide a relatively easy way to summarize the major points in NASP's *Ethics*. One should always place the welfare of the student/client over one's own interest or convenience. One must achieve competence in an area before offering it to the public and must continually upgrade skills to maintain that competence. Relationships with other professionals should be based on openness, honesty, and the logical consideration of facts over defensive emotions. As a member of the larger community, one may press for change through the political process, but only in a lawful, conservative manner that does not reflect badly on school psychology.

If this sounds rather difficult and one-sided . . . it is! The intention is to protect the public, and all of the responsibility falls on the individual school psychologist. As summarized so clearly by Jacob and Hartshorne (1992), "Professionals do not have rights under a code of ethics, only obligations" (p. 21).

BEST PRACTICES

Prepare in Advance

As mentioned above, it is preferable to prevent problems than to deal with them. Colleagues and one's hiring agency need to be fully informed regarding one's training, experience, theoretical orientation, personal limitations, and ethical beliefs. For example, NASP's *Ethics* calls on school psychologists to act as advocates for their students/clients. This position can cause the school psychologist to function as the "conscience of the school" (Dawson, 1992), perhaps in the face of pressure from colleagues to recommend what would be easiest for the educational system. If all parties knew in advance that the school psychologist would take this role, there would be less of a surprise and a better chance to resolve any conflicts in a manner that benefits the student.

NASP documents, such as the *Professional Conduct Manual* (1992b), are relatively inexpensive and may be used during the "prior notice" phase. Colleagues and supervisors, particularly those who are not school psychologists or not NASP members, should have copies of *Ethics* and of *Standards* on their desks for reference. Should one be forced by circumstances to take a stance based on principle, it would be nice for one's employer to understand and support the action because of discussions and manuscripts provided in advance. Another publication that may be helpful is the *Self-Evaluation Manual*, created by Virginia Smith-Harvey (1991) which is based on NASP's *Standards*. This document can assist a school psychology department in conducting an evaluation of services to see how well current practice matches NASP's recommendations. The resulting report may help administrators to better understand how a school psychology unit should operate, and to provide a clear direction for the improvement of services.

Always Be on the Alert

As mentioned before, situations that can draw one into unethical practice tend to arise suddenly and may initially appear benign. First of all, school psychologists need to study NASP's *Ethics* thoroughly to gain an understanding in depth of what is required. Second, they need to be always on the alert for detrimental practice. Finally, they need to act conservatively, thoroughly evaluating situations before taking action.

Seek Assistance

There may be times when the proper course of action is unclear. A school psychologist may find himself or herself caught in a web of conflicting loyalties, laws, and policies. Under these conditions, it is proper to write the Ethical and Professional Standards (E&PS) Committee for an opinion. Simply describe the situation in detail, and ask the committee for an opinion about the best way to proceed. Sometimes a more experienced school psychologist on your staff, a qualified supervisor of school psychological services, or the chairperson of the Ethical Standards committee of your state affiliate association can provide the guidance you seek.

If You Suspect Unethical Practice

A time may come when the actions of a fellow school psychologist appear to be in violation of professional ethics. NASP members, and members of the National Certification System, are required to take steps in an attempt to correct such a situation. It is never easy to face a colleague with a serious concern. But if the potentially unethical practice is allowed to continue, it may result in damage to students and the reputation of the profession. Uncomfortable as it may be, the concerns must be raised.

Several sections of NASP's *Ethics* explain how to proceed. In Section III-A-7, school psychologists who suspect "detrimental or unethical practice" (p. 7) are told to attempt to rectify the situation informally. This means having a private, serious talk with the individual engaged in the practice. Whether the practitioner is a NASP member or not, bring along the appropriate sections of the *Professional Conduct Manual*. It often helps to begin and end a difficult conversation with statements of appreciation, thus placing the "bad news" in the middle. This is sometimes known as the "sandwich method." Using this technique, a hypothetical discussion might begin like this:

> Joe, I've worked with you here at the Anytown School District for 10 years or so, and I've always admired your work. You might say I've used you as a role model and tried to match your high standards. But I've noticed that you are dating a high school student — somebody young enough to be your daughter — and what's more, she is somebody that you see in counseling. I'm worried about how all of this might turn out; both you and the student could be hurt very badly. Plus, I've been reading the ethical standards for both NASP and that counseling association you belong to — based on those standards I'm convinced this type of behavior is unethical. You are too valuable to this school district and you do too many good things for the students you see. And I would hate to lose you as a colleague . . .

If the situation of concern is not a clear violation of ethical principles, it may be helpful for both individuals to jointly approach the Ethical and Professional Standards Committee for an opinion. By asking for an opinion together, one avoids the adversarial aspects of filing a formal complaint. The atmosphere is more one of collegiality, with individuals of two opposing viewpoints seeking resolution through consultation with an outside party. Should the situation deteriorate to the point that a complaint would need to be filed, that step is still available.

Should all informal attempts prove unfruitful, the process would move to the next level. The school psychologist who had observed the detrimental practice would file a written complaint with the appropriate professional association (*Ethics* III-F-7). These procedures vary across groups, so some background investigation into the proper method may be required. If the person in violation does not belong to a professional organization, one should complain to the hiring agency. The complaint should be in writing, provide explicit examples of offenses instead of generalities, and reference the sections of the ethical standards that seem to have been violated. The complaint will need to be signed, as anonymous complaints cannot be accepted.

The filing of an ethical complaint is an extremely serious step. It should be done to help a recalcitrant colleague to understand the seriousness of the malfeasance and take corrective actions. The purpose is to protect the public and the profession by policing a wayward member. Whenever possible, NASP's Ethical and Professional Standards Committee attempts to resolve such situations by educating the member regarding appropriate practice. If this is not possible, a variety of sanctions may be imposed, including expulsion from the Association.

The full process is rather involved and will not be described in detail here. The adjudication proceedings are based upon providing complete due process for members, so there are checks, balances, and appeals at every step of the way. The E&PS committee has a good record of rectifying conflicts at the educative level, with very few complaints needing to go to expulsion. In situations in which the committee believes that the welfare of the public is at stake, NASP will notify other interested parties about the final outcome of the case. For example, NASP could notify one's employer or the state certification/licensure board, which implies a potential loss of employment.

On occasion, school psychologists may experience strong conflicts with colleagues or parents. If the individual leaves feeling angry and helpless, s/he may cast about for a way to get even. Filing a complaint of ethical misconduct, even an unfounded complaint, will fill some individuals' need for revenge. Since school psychologists as professionals are jealous of others' good opinion of their conduct, simply having charges brought against them can be a shocking experience that creates self-doubt, embarrassment, and fear of wrongful punishment. We cannot prevent members of the public from taking this course of action; we can only trust that the truth will be revealed as the E&PS committee follows the prescribed procedures. There is a section in *Ethics* (III-7-b) that forbids NASP members from filing a charge "that is frivolous or motivated by revenge" (p. 7).

Special Responsibilities of Private Practice

School psychologists who provide services through a private practice take on additional responsibilities designed to protect the public. This is especially critical for simultaneous practice in both the public and the private sectors. Section V-A-1 of *Ethics* requires private practitioners to take full responsibility, and to inform the consumer of any potential difficulties. Under these guidelines, if any ethical problems arise, it is always the fault of the private practitioner.

Although this rule may seem excessively harsh, it is built on a simple premise: The consumer enters the market with vastly less knowledge and information than the private practitioner. In order for the consumer to make an informed judgment about services, the critical facts must be provided by the private practitioner. Full disclosure to such a high degree will undoubtedly upset those who incline to high-pressure sales, and will ultimately cause the ethical private practitioner in effect to turn away clients.

For example, a school psychologist working in the private sector may not charge a client for the same service that a school psychologist would provide free of charge through the public sector (*Ethics* V-A-2). In fact, the private sector school psychologist is required to inform the client that the same services are available free of charge through the public schools (*Ethics* (V-A-3). Just imagine the pressure on a new, "hungry" private practitioner who has to tell a potential customer that the same service is available free!

Private practice and public service are required to be kept separate (*Ethics* V-A-4, 5). Great difficulty in following this standard is possible if one's private practice is physically near one's public service. Even though the private practice may be conducted on weekends or evenings in another town, the private clients could very easily know how to contact the school psychologist during the day. Even if they were instructed not to call during working hours, a crisis might require private clients to call the school psychologist at the public school. Now we have an unethical conducting of private business on public time! Despite all efforts to avoid this situation, it is almost impossible unless practice sites and the nature of the services are widely separated.

CASE STUDIES

Thinking analytically about ethics is a skill that is developed with practice. To provide members with a model for this type of problem solving, the NASP newsletter, *The Communiqué* occasionally presents an Ethical Dilemma column. The feature describes a "sticky situation" and then invites NASP members to render an opinion regarding the appropriate course of action. Reviewing another person's thinking in a case study can be a fun and informative way to become more knowledgeable about professional conduct. Summarized below are two examples.

Blanket Permission for Services

In an attempt to be efficient, a school psychologist hired to provide counseling and consultation sends a letter to all parents announcing the availability of services. The letter asks all those who would object to services to contact the school psychologist. Hearing no complaints, the school psychologist will assume that permission is granted.

For this column, Lane Roosa, John H. Correll, Carol Osip, and John Reinhardt provided opinions. They all began their responses by determining the key elements of the situation — in this case, whether informed consent was obtained through the use of a general announcement. They then studied NASP's *Ethics* and *Standards* for sections that would pertain. Although the exact wording and section numbering has changed a bit over the years, all of the respondents found passages that require the active involve-

BEST COPY AVAILABLE

ment of the parents. They also considered relevant laws, such as the Family Educational Rights and Privacy Act (Rules and Regulations, 1982). They considered crisis situations, and involvement in the reporting of potential abuse. Putting all of that information together, the authors all concluded that the "call me if you object" shortcut is unwise, does not necessarily lead to the provision of high-quality service, and could actually create more time-consuming trouble than was saved (Canter, 1989, p. 9). In terms of our four broad themes, the blanket permission does not adequately protect the welfare of the client, and it suggests reduced professional competence. The intent — increased efficiency — is laudable, but the practice falls short of attaining that goal.

Pressure to Provide a New Service

Fred Grossman responded to a situation posed in a *Communiqué* Ethical Dilemma column, which involved an administrator who insisted that a school psychologist provide a new service. The problem: The school psychologist has had no training or experience in that area. The administrator insists and suggests that the school psychologist's job is at stake if the service is not provided.

Grossman quickly pinpointed the issue of professional competence. He consulted NASP's *Ethics* and *Standards*, and a position statement recently issued by the Oregon School Psychologists' Association, "On Performing Within the Bounds of One's Competence" (Professional Standards Committee, 1992). These documents clearly forbid providing services for which a recognized level of competence has not been achieved. Expanding on his assignment, he then produced four suggestions for dealing with the situation: (a) Notify all relevant parties in advance of areas of competence; (b) make referrals to trained professionals for those services that are outside of one's own area of training; (c) consult and collaborate with practitioners in other professions to supplement one's own training; and (d) obtain the training necessary to ethically provide the requested service. This example touches upon all four of the broad themes noted above: welfare of the client, professional competence, integrity of professional relationships, and responsibility to the community/society.

These case studies demonstrate a particular style of problem solving. It involves thinking very specifically about the critical aspects of a problematic situation in order to describe the problem concisely. In the context of a broader focus of attention, relevant documents relating to ethics, standards, and statutes are studied in a hunt for applicable sections. The final analysis attempts to apply logic and reason to a human predicament that might be fraught with emotion. The end result should meet the standard recommended by Haas and Malouf (1989):

> 1. The decision is *principled*, that is, based on generally accepted ethical principles.
>
> 2. The action is a *reasoned* outcome of a consideration of the principles.
>
> 3. The decision is *universalizable* [sic], that is, the psychologist would recommend the same course of action to others in a similar situation. (pp. 2–3).

SUMMARY

Many of the actions that help to identify a professional as a school psychologist are specified in NASP's *Professional Conduct Manual*, a publication that contains the *Principles for Professional Ethics*, and the *Standards for the Provision of School Psychological Services*. There are other sources of advice, such as "best practices" publications, school district policies and procedures manuals, and state and federal laws. When the guidance is conflicting, NASP considers the general principles described in *Ethics* to be the authority, and will take alleged violators through an adjudication process to enforce prescriptions in *Ethics*. *Standards* documents are not enforced, but NASP encourages all members "to work towards achieving the hallmarks of quality services delivery that are described therein" (NASP, 1992b, p. 5).

Although many of the principles seem to be simply common sense, they require study and reflection. The injunctions in *Ethics* are written in general terms, for the most part, and their application to a specific situation in a particular place of employment may not be immediately clear. Furthermore, is it more likely that school psychologists will encounter several subtle situations on a daily basis than the occasional blatant disregard for ethics. This requires us to be constantly evaluating our performance in respect to what is considered to be ethical.

By announcing our capabilities and ethical responsibilities in advance, school psychologists can avoid many of the smaller problems that are caused when others make inaccurate assumptions about the role and function of school psychologists. NASP prints several reference books that are often valuable for informing supervisors and for providing support for appropriate, but perhaps unpopular, actions (Knoff, 1989).

Ethical behavior tends to be that which (a) places the welfare of the client above the convenience of the practitioner; (b) is limited to the provision of services for which the school psychologist has achieved a recognized level of competence; (c) maintains honest and respectful relationships with other professionals; and (d) works to improve conditions within schools, the profession, and the community in general. When circumstances are murky, assistance in determining what is ethical is available from the NASP Ethical and Professional Standards Committee, or the Professional Standards committees of the state affiliates of NASP. Case studies provide a means for learning how to apply a problem-solving methodology when analyzing an ethical dilemma.

When potentially unethical practice occurs, the school psychologist should attempt to resolve the conflict by using informal means. If this proves to be unsuccessful, a formal complaint should be filed with the appropriate professional association. NASP's complaint procedures attempt to educate rather than adjudicate, and they are characterized by a respect for maintaining a member's confidentiality and due process rights.

This chapter deals very briefly with professional ethics, providing only a starting point for study. This may not be the most entertaining or exciting reading in the professional literature, but every practitioner will regularly encounter situations requiring a decision based on ethical principles. By preparing in advance for these situations, we will be confident in our ability to proceed in a manner that protects clients, ourselves, and ultimately ensures high-quality school psychology services.

This is the APA's stand on ethics; it is interesting to notice the similarities to and differences from NASP's positions.

Jacob, S., & Hartshorne, T. (1992). *Ethics and law for school psychologists.* Brandon, VT: Clinical Psychology Publishing Co.
An excellent, comprehensive textbook. This book was in publication prior to NASP's most recent revision of *Ethics*, so an outdated version appears in the appendix.

National Association of School Psychologists. (1992). *Professional Conduct Manual.* Silver Spring, MD: Author.
This booklet contains both the *Principles for Professional Ethics* and the *Standards for the Provision of School Psychological Services.* It is your primary reference. Supervisors and administrators, particularly those who do not have a background in school psychology, should have a copy.

Various editions of the NASP newsletter, *The Communiqué,* contain the Ethical Dilemma column. These provide good examples of the application of a problem-solving approach to the analysis of difficult ethical situations.

Your school board and state board of psychology examiners may have policy documents that describe their interpretation of ethical professional behavior. Even though NASP believes its documents supersede all others, it is in your best interest to be knowledgeable about them.

Best Practices in School Psychology and the Law

David P. Prasse
Governors State University

OVERVIEW

School psychology has been influenced by various legal sources including legislation and judicial decision. Such influences are on the rise and bringing with them an inevitable professional and public scrutiny of the disciplines' practices and policies. While many components of psychology and education are subject to legally defined parameters, school psychology, due in part to historical ties to special education, has realized a significant legal impact that has modified roles, responsibilities, and the overall delivery of school psychological services.

As the programs and practices of education have undergone radical change as a result of judicial and legislative influence, so too has the service delivery components of school psychology. Courts, in their role as mediator between the rights of students and parents and the rights/responsibilities of schools, have moved to protect and define procedural and substantive due process for students, especially students with disabilities. Courts have instructed school systems to provide special education programs where there has been an absence of programs or where inappropriate programs have not met the educational needs of students. The legislative influence of Public Laws 94-142 and 99-457 and Section 504 of the Rehabilitation Act and, more recently, PL 101-476, the Individuals with Disabilities Education Act, are known to us all. Much of the legal influence on the discipline of school psychology is a result of these federal acts and similar state-based legislation. Recognizing the sources of legal influence on school psychology is fundamental to a comprehensive knowledge of "best practices."

As the legal parameters change, so too does the school psychology/law relationship. This constant state of flux means that what is mandated or required today may change tomorrow. A practice or process followed yesterday may be judged inappropriate or illegal in the future! As societal priorities change and individual rights are further defined, legal requirements change and the parameters of influence expand and/or constrict. While there exists "fundamentals" of law that mostly remain stable across time, the daily practices and service delivery approaches are susceptible to legislative and judicial interpretation of those fundamentals.

What follows is a foundation for best practice. The purpose is to indicate what is known about the influence of law on school psychology and therefore what all school psychologists are expected to know and understand. The intent is not to provide detail about the specifics of best practice. Rather it is to highlight the areas of knowledge regarding school psychology and the law that should be known to all who practice school psychology.

BASIC CONSIDERATIONS: SOURCES OF LEGAL INFLUENCE

There exists a sequential nature to sources of law that reflect (in most cases) application of broad principles to specific situations. It is expected that specific laws, practices, and procedures be consistent with broad principles. Understanding the broad principles provides the foundation upon which we problem solve specific situations. The sources of law are for the most part hierarchical and are pictured as follows:

Federal Constitution

Federal Statute

State Constitution

State Statute

Administrative Rules

Local Policy and Procedure

Sources of law are more influential (i.e., having greater impact) the higher they are in the hierarchy. They are also sequentially subordinate, and those that exist beneath others are narrower in scope and applicability. However, on occasion these lower order sources may be no less important than those sources higher in the hierarchy.

Constitution

The cornerstone of all law is the Constitution of the United States. Sources of law (federal and state statutes, judicial decisions, etc.) are subject to the provisions of the Constitution. Laws, practices, and procedures not congruent with principles established by the Constitution are eventually judged (usually by a court) as unacceptable.

The U.S. Constitution has nothing directly to say about education yet everything to say about the manner in which education (including school psychological services) is provided to the public. There is no constitutional right or guarantee to an education. Providing an education to the public is a matter left to the individual states by way of the Tenth Amendment which states:

> The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively.

Therefore, states may provide a public education to its citizens. In so doing, the state must do so in a manner that is compatible with the principles established by the Constitution.

It is this requirement that impacts the delivery of school psychological services. As an aspect of public education, school psychological services must adhere (as education in general) to established constitutional principles. When the practices and procedures of school psychology violate those principles, they will likely be viewed as unacceptable. Knowledge of these fundamental constitutional principles and the legislation and litigation that builds on them is necessary to effective problem solving when weighing the legal parameters associated with delivering school psychological services.

Legislation

Legislation, or statute, is the most influential source of law affecting the delivery of educational and school psychological services. Enacted by Congress or state legislatures, legislation is created to provide the mechanism for implementing constitutional guarantees or for the purpose of initiating specific programs. Federal legislation important to school psychology is either program legislation or civil rights legislation. Program legislation provides funds for delivering specific programs (e.g., Chapter I, Special Education) and in providing these funds mandates that agencies delivering the services do so in a manner prescribed by the legislation. The Individuals with Disabilities Act of 1990 (PL 101-476, IDEA) is among the most widely known. Its precursor was the Education for All Handicapped Children Act of 1975 (PL 94-142, EAHCA or EHA). Through IDEA funds are made available for educating children with disabilities. The procedures by which these educational services are delivered are specified by the legislation and recipients are obligated to comply with the requirements. Civil rights legislation differs in that requirements are usually not tied to program funding; that is, procedures mandated by the law must be adhered to even in the absence of funds tied directly to a program. Section 504 of the Rehabilitation Act of 1973 is a relevant example of this type of legislation.

State statutes serve to enact the principles established by a state constitution or federal mandate and may be quite specific and detailed. For example, most states have a compulsory school attendance law and a law that provides for educating children with disabilities. The later must be compatible with constitutional principles and requirements delineated in IDEA and Section 504. State laws affecting education are wide ranging and differ from state to state. For example, mandatory child abuse reporting laws may or may not detail the precise steps necessary for reporting suspected abuse. Direct and indirect impact on school psychology will vary accordingly.

Administrative Rules

When a law is enacted, a specific governmental agency is charged with implementing the requirements of the statute. Inasmuch as the legislation may not include all the specific details necessary for successful implementation, the appropriate governmental agency is empowered to write rules to accompany the newly enacted law. When adopted, these rules are equivalent in importance and influence as the statute itself. At the federal level, a statute pertaining to education is usually administered by the Department of Education, which is then responsible for developing corresponding rules. At the state level, the relevant agency is frequently the Department of Public Instruction or Education which has similar responsibilities to those found at the federal level. These governmental agencies will usually "propose" rules, hold public hearings, and finally adopt the rules. Paying close attention to the rule-making process as well as possessing a thorough knowledge of the final rules is a necessary and crucial component for understanding the intent and specific requirements of a particular law.

Litigation

Litigation is the source of and knowledge base for law referred to as case law, and the influence of judicial decision making is predicated, in part, on the judicial structure itself. There exists a federal court system and individual state court systems. The federal system includes three levels: U.S. District Courts (trial courts), U.S. Court of Appeals (11 circuits), and the U.S. Supreme Court (Court of last resort). Generally, the federal judicial system is used when the question involves a constitutional issue or a federal statute. Each state has its own judicial system and each system varies greatly. Like the federal system, states have different levels often including circuit courts, one or two levels of appellate courts, and a "supreme" court.

The import of a judicial decision depends, in part, on the level of court in which the issue is adjudicated. Generally, the higher a court is in the system, the greater the impact or influence. For example, a state supreme court decision is applicable to that particular state, while a decision rendered by a U.S. Court of Appeals is applicable to that entire district which, except for the District of Columbia and one dealing with special patents and copyright issues, includes several states. Decisions of the Supreme Court are applicable to all states and effectively become the law of the land. So the higher the court in the judicial hierarchy the more authoritative its decision and accompanying opinion.

The fundamental purpose of judicial decision is to resolve conflict — conflict that arises from two different interpretations of a statute or from questions embodied in a state or the federal Constitution. Judicial decisions involve determining the intent of the legislature and the compatibility of that intent and/or practices with constitutional principles. Statutes or practices that violate constitutional principles are then overturned or modified by the court. The potential impact or influence of case law is thus twofold. First, the jurisdiction of the court (where it is in the hierarchy) determines the influence of the decision. Second is the cumulative influence established through a series of decisions that when taken together establish a clear and unequivocal trend, pattern, or precedent.

Professional Standards and Ethical Code

Professional standards or ethical codes represent an additional (albeit indirect) source of legal influence on the discipline of school psychology. (See Bower this volume for coverage of ethical practice.) The standards that directly bear on school psychology include the National Association of School Psychologists (NASP) *Principles for Professional Ethics* (1992), *Ethical Principles of Psychologists and Code of Conduct* (American Psychological Association [APA], 1992), *Specialty Guidelines for the Delivery of Services by School Psychologists* (APA, 1981), and *Standards for Educational and Psychological Testing* (APA, 1984). In addition, most state school psychology associations have adopted professional practice codes.

Although important to the overall process of shaping and monitoring behavior of school psychologists, professional standards are not, at least in the traditional sense, "the law" and therefore do not carry similar weight, or influence as statutes or case law. Professional standards interface with the law and in so doing are not free to develop from discipline preferences alone. The existence of a standard in the NASP *Principles* that states, "School psychologists avoid any action that could violate or diminish civil and legal rights of clients" is clear acknowledgment of this interface.

Nonetheless, standards are important to the profession (including the consumers of services) in that they represent consensual thinking with respect to "best practices." They become the means by which professional behavior is judged by both peers and on occasion the courts. Courts have and continue to refer to professional standards when reviewing the behavior of an individual psychologist and when reviewing the procedures and policies of service delivery systems. In the legal arena, the "clout" of professional standards may be described as a dynamic state of potential. That is, if a court considers professional standards during deliberations and bases decisions (even in part) on professional standards, then those standards become (at least in that particular case) like the law. The more times that occurs, the stronger is the "legal" influence of professional standards.

BASIC PRINCIPLES: FOUNDATIONS FOR PROBLEM SOLVING

Attempts to define or describe best practice with respect to school psychology and the law is challenging for two reasons. First, as stated earlier, law or legal influence is dynamic. Requirements, restrictions, and parameters around professional practice change, sometimes with short notice. Second, legal influence on practice is subject to interpretation. Professional opinions (both psychologists and lawyers) differ with regard not only to basic legal principles but also to how specific requirements should be implemented. The "correct way" to deliver services is then open to debate.

What should be known by school psychologists about the law is traced to a few important sources. They are fundamental, for they serve as the basis for day-by-day problem solving. They include an understanding of specific components of the Constitution, certain procedures and principles that flow from it, an understanding of children's rights, and finally, specifics of relevant legislation and litigation. We turn first to the Constitution.

The Constitutional Foundation

A theme that permeates discussion with respect to legal requirements and mandates for school psychology is "May we do this?" or "Will I be held liable for this?" Problem solving is, in large part, dependent on understanding the *intent* of the law (case or statute) which emanates from fundamental constitutional principles. To understand these principles is to know the foundation for judicial decision, which provides a base on which specific practice questions are answered.

The constitutional principles relevant to judicial decisions and legislation are relatively few in number. As indicated earlier, it is the Tenth Amendment that establishes education as a state function. Other relevant Amendments include the First and Fourteenth. The Fourteenth Amendment has been most influential with respect to special education and school psychological services, for many court decisions that have clarified the rights of children and educational practice have, in large part, been based on this Amendment. The Fourteenth Amendment states, in part:

> No state shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty, or property without due process of law, nor deny to any person within its jurisdiction the equal protection of the laws.

Application of the Fourteenth Amendment to education and school psychology is understood through a brief elaboration of two clauses: the *due process* clause and the *equal protection* clause. Application of the Fourteenth Amendment by courts means that most actions respecting children with disabilities (or suspected disabilities) must guarantee procedural and substantive due process and equal protection. Procedural due process guarantees a person the right and meaningful opportunity to protest and be heard before government (in this case schools) may take action with respect to them. Substantive due process establishes that there are certain rights and privileges that a state may not arbitrarily take from a citizen (in this case student or parent) and that the state may not act unreasonably, arbitrarily, or capriciously in dealing with a citizen. Equal protection guarantees to a person the same rights and benefits all other citizens enjoy with respect to their government (e.g., schools) unless the withholding of those rights and benefits is for a valid reason that justifies the state in singling out the person for differential treatment.

Judicial application and interpretation of the Fourteenth Amendment is a continuous and dynamic process. Court decisions range from establishing an equal educational opportunity for persons with disabilities to mandating assessment practices that do not result in disproportionate placement or overrepresentation of minorities. Among the procedures affecting school psychological services required by dint of the Fourteenth Amendment are

- Written notice to parents if a school proposes to change, or refuses to change, the identification, evaluation, or educational placement of the child.
- Providing parents an opportunity to present complaints with respect to any matter relating to the identification, evaluation, or educational placement of their child.
- Procedural requirements of informed written consent prior to assessment and special class programming.
- All requirements specific to nondiscriminatory assessment.

Application of the Fourteenth Amendment to the educational arena for children with disabilities resulted in dramatic change: It opened the schoolhouse doors to children with disabilities. However, children with disabilities would not see those doors open wide until a broader "right to an education" was established under our Constitution for all children.

The right to an education. As stated earlier, there is no federal constitutional right to an education. However, when states choose to provide an education to its citizens (as all states do), they must do so in a manner acceptable to fundamental constitutional provisions. Judicial intrusion into the educational arena has been mixed. However, the cornerstone for providing an equal educational opportunity for all children, including those with disabilities, is *Brown v. Board of Education* (1954). Reversing almost 60 years of judicially supported segregation, (*Plessy v. Ferguson*, 1896), *Brown* addressed the applicability of the equal protection clause to public education. The *Brown* decision established that educating minority children in separate but "equal" facilities violated the equal protection clause of the Fourteenth Amendment and therefore denied them an equal educational opportunity. The thinking of the Supreme Court was that education became a property interest when states made it available to its citizens and separate but equal was inherently unequal.

When the Court found this practice violated the equal protection clause, it established the foundation upon which the exclusion of children with disabilities from school would subsequently be challenged. That challenge was helped by the Court's decision in *Brown* which made clear the applicability of the Fourteenth Amendment to the public school arena. Indeed, the rationale and precedent established by the Court should be critically considered as potentially applicable to the current debate surrounding inclusion. It was against the backdrop of *Brown* and the political promise of equality and equal opportunity emerging in the 1950s and 1960s that the hope for educating children with disabilities emerged.

Program availability. Legal influence on educational programming is an outgrowth of litigation involving the provision of educational services to children with disabilities. It was litigation and later legislation that resulted in various mandates to provide an education to children, particularly the child with disabilities. The legal foundation for requiring equal educational opportunity for children with disabilities is the equal protection clause. By applying the equal protection clause of the Fourteenth Amendment to education, courts created the fundamental concept of an equal educational opportunity, thereby precluding states from excluding from its schools children with disabilities. For many years children with disabilities were excluded from public schools — often shut out of school altogether or shunted to inappropriate institutions.

The precedent-setting cases challenging school systems and states that systematically denied a free public education to individuals with disabilities include PARC (*Pennsylvania Association for Retarded Citizens [PARC] v. Commonwealth of Pennsylvania* [1972]) and *Mills v. Board of Education of the District of Columbia* (1972). *PARC* challenged the exclusion from school of children deemed to be uneducable or unable to profit from an education on the basis that such exclusion violated their equal protection and due process rights. Settled by consent decree in favor of the children, the case, receiving national media attention, served as an impetus for similar litigation throughout the country.

The children represented in *Mills* were denied an equal educational opportunity as a result of their various handicapping conditions and the District denied them an education by utilizing procedures of suspension, exclusion, and class reassignment. In addition, their due process rights were denied when the District assigned them to special classes, precluding them from access to regular education programs. In finding for the plaintiffs the court dismissed limited financial resources as a basis for the denial of equal educational opportunity and ordered an equal expenditure of funds so that no child would be excluded from a publicly supported education. *Mills*, unlike *PARC*, applied not only to mental retardation, but to other handicapping conditions as well. Together these cases served as a basis for the development of federal legislation, particularly PL 94-142, requiring equal educational opportunity for children with disabilities. Indeed it was the due process provisions of *Mills* that served as the foundation for the specific requirements that were to emerge in the Education for All Handicapped Children Act of 1975 (EAHCA).

The Legislative Foundation

Although pervasive in their impact on school psychological services, the federal laws that shape daily practice are actually few in number. They are however comprehensive and detailed in coverage and, more so than any other source, have influenced the practices and procedures of school psychology. Earlier program or funding legislation was distinguished from civil rights or antidiscrimination legislation. The statutory provisions of Section 504 of the Rehabilitation Act, for example, are requirements that attempt to ensure disabled persons are not discriminated against.

Section 504 of the Rehabilitation Act. Adopted in 1973 as an amendment to an older law that focused on vocational rehabilitation regarding employment, the 1973 Rehabilitation Act provided that recipients of federal financial assistance could not discriminate on the basis of a handicap. Although adopted in 1973, the implementing regulations were not approved until 1977. Section 504 (as it is often referred to) is civil rights legislation and similar therefore to other antidiscrimination legislation such as that dealing with race (Title VI) and gender (Title IX). Ensuring compliance is then the responsibility of the Office of Civil Rights, not the U.S. Department of Education. The overarching requirement is that *all* recipients of federal funds not discriminate against an otherwise qualified disabled individual on the basis of disability. As such, requirements extend to many institutions (public and private) including business, health care, and of course schools.

Section 504 defines a disabled person as follows:

> any person who (i) has a physical or mental impairment which substantially limits one or more of such person's major life activities, (ii) has a record of such an impairment, or (iii) is regarded as having such an impairment. [29 U.S.C. Sec. 706(7) (B)].

Physical or mental impairment includes physiological disorders or conditions, including cosmetic disfigurement, and mental or psychological disorders include mental retardation, organic brain syndrome, emotional or mental illness, and specific learning disabilities. Major life activities are "functions such as caring for one's self, performing manual tasks, walking, seeing, hearing, speaking, breathing, learning and working" (34 C.F.R. Part. 104.3).

Section 504 (Subpart D) requires that districts provide a "free appropriate public education" (FAPE) to each qualified person with a disability, regardless of the nature or severity of the disability. Districts are required to provide a full range of special accommodations and services necessary for students with disabilities to participate in and benefit from public education programs and activities.

Under Section 504 a free appropriate public education requires districts to follow procedures that ensure

- Nondiscriminatory evaluation and placement procedures.
- Periodic re-evaluation of students with disabilities.
- Educational services that meet individual educational needs.
- Educational services equal in quality to that provided for nondisabled students.
- To the maximum extent possible, the education of disabled students with nondisabled students.

- Due process procedures that ensure parent participation in evaluation and placement decisions and provide for an impartial hearing with parent representation by counsel.

A determination under Section 504 that a student has a disability does not necessarily mean that the student would be deemed disabled according to the criteria specified under IDEA. In those cases, students' educational needs must be provided for by regular education programs and their specific individualized educational needs met through the resources of regular education.

Individuals with Disabilities Education Act (IDEA). Triggered, in part, by the litigation of *PARC* and *Mills*, Congress, in 1974, passed a funding bill that required states to adopt goals that would ensure providing full educational opportunities to all handicapped children. Establishing such goals was a condition for receiving federal funds (PL 93-380). The following year Congress passed the Education for All Handicapped Children Act (EAHCA) which became effective in 1977. Finally, in 1990, Congress amended the EAHCA and retitled the law as the Individuals with Disabilities Act (IDEA; PL 101-476, 20 U.S.C. Sec. 1400 [a]).

The adoption of legislation mandating an equal educational opportunity to students with disabilities brought with it cornerstones of service delivery that continue to shape the practice and procedures for delivering both special education and school psychology services. These cornerstones remain the foundation for problem solving many of the questions that arise about delivering services to disabled students. These broad principles help us understand what is operationally meant by a free appropriate public education.

Zero reject. IDEA (as well as Section 504) makes it clear that all children are to be afforded an equal educational opportunity and states may not deny an education on the basis of a disability. Further, the law requires that states be affirmative in seeking out those who are disabled through "child find" activities. Extending an education to all disabled students today means those eligible individuals from birth through age 21. In addition, the severity of the disability is not a reason to deny an otherwise eligible student an education. As a result, the definition of education has been expanded to include even basic and fundamental life skills such as feeding and toilet training. Students may not be excluded from school only on the basis of a disability, and if a student's behavior at school is disruptive yet caused by the disability, schools remain obligated to provide for the student's education (Buesing & Prasse, 1991).

Appropriate education. Since the adoption of the federal law requiring public schools to provide an equal education opportunity to students with disabilities, the notion of what is an appropriate education has proven to be one of the most dynamic and evolving principles of the law. Professionals have debated issues of appropriate education in the literature while courts have rendered increasingly specific decisions that further define what is meant by appropriate.

To help determine what is appropriate, courts have turned to two key components required of districts when implementing FAPE. They are the *Individualized Education Program* (IEP) and *Least Restrictive Environment*. As a requirement of IDEA, the legal definition of an IEP means a written statement for a child with a disability that includes specific statements about a student's current educational level, annual goals, specific educational and related services, dates for initiation and anticipated duration, objective criteria for measuring the annual goals, and evaluation procedures. Least restrictive environment requires "that to the maximum extent appropriate, handicapped children, including children in public or private institutions or other care facilities are educated with children who are not handicapped" (34 C.F.R. Sec. 300.551[b] [1]). The legal definition continues with a requirement that "special classes, separate schooling or other removal of handicapped children from the regular educational environment occurs only when the nature or severity of the handicap is such that education in regular classes with the use of supplementary aids and services cannot be achieved satisfactorily" (34 C.F.R. Sec. 300.551[b] [2]).

Individualized Education Program. The requirement that a school district develop a plan unique (individualized) to the student's educational needs that includes goals, objectives, and time lines for implementation has been used by the Supreme Court as one basis by which to judge the congressional intent of the meaning of an appropriate education. In *Board v. Rowley* (1982) the Supreme Court dealt for the first time with the question of what constitutes an appropriate education. Deciding whether a deaf child required an interpreter (as a related service) the Court ruled that the interpreter was not required under the law. In reaching this decision the Court emphasized the legislative history of P.L. 94-142 and concluded that the intention of Congress was not to maximize development of students with disabilities. Rather it was to grant access to educational opportunity and provide a reasonable opportunity to learn. Noting that the student had learned and progressed from grade to grade the Court concluded the district had satisfied the intent of what is referred to as the "open door" policy, or in other words provide comparable treatment. Therefore, in the opinion of the Court the intent of IDEA is to provide a reasonable opportunity for a student to learn, not necessarily to maximize their potential.

The relevance of *Rowley* to the IEP and an appropriate education is noted when the Court affirmed what might be termed a process definition of the IEP. That is, if the IEP is developed procedurally in a manner compatible with the requirements of IDEA it will be deemed appropriate. An IEP developed by a group of professionals and parents is the basis or cornerstone for individualizing an education program. The *Rowley* decision affirmed that what was meant by appropriate education is gleaned from an overall understanding of IDEA which emphasizes process and inputs rather than results and outputs (Turnbull, 1986).

The relevance of the IEP to judging an appropriate education was strengthened in *Irving Independent School District v. Tatro* (1984). The fundamental question involved was whether Clean Intermittent Catheterization (CIC) was a necessary related service, or was it excluded as a medical service as is provided under IDEA. The child in question had spina bifida with orthopedic impairments. She required CIC assistance during the school day. The requirement was not mentioned as a component of the IEP and the district refused to administer it.

The Court affirmed the Tatro's claim that their child was entitled to CIC. The Court ruled that CIC is a related service as defined under IDEA, for it is a service which provides a meaningful access to an education. Necessary to the decision was to rule CIC a school health service and not a medical service.

With regard to an appropriate education the implication of the *Tatro* decision is two fold. First the decision affirms judicial review regarding the appropriateness of the IEP. Going therefore a step beyond *Rowley*, the Court made clear their intent to judge the appropriate education standard not only on the basis of adherence to procedural safeguards but on the basis of substance and content as well. The Court did review the content and substance of the IEP and found it wanting. Second, the decision serves to broaden the construct of related services to enable the child not only to benefit from but also to obtain access to educational services.

Least restrictive environment. The judicial cornerstone for educating children with disabilities with children who are not is over 40 years old, for it was *Brown v. Board of Education* (1954) that applied the equal protection clause of the Fourteenth Amendment to the issue of racial segregation in our public schools. Holding that separation is inherently unequal, the Supreme Court set forth the argument that education, when guaranteed by a state, is a property interest and must therefore be delivered in a manner that affords due process of law and equal protection of the laws. The principles set forth in *Brown* became the basis for subsequent litigation that forced the public schools to extend an equal educational opportunity to children with disabilities (*PARC v. Pennsylvania*, 1972; *Mills v. Board of Education*, 1972).

Separating children (either on the basis of race or disability) became then a practice that was considered unacceptable, if not illegal, and at both the state and federal level, legislation emerged that not only required an equal educational opportunity for the disabled student but also required that it be delivered in a "least restrictive environment." The requirement is nested in the judicial holding that separate is not equal and separation stigmatizes. In addition, interacting with nondisabled peers is considered an essential activity in the education and development of disabled students.

The consideration of the least-restrictive-environment variable in the appropriate education equation has proven to be one of the most challenging and continuously changing professional requirements. Even the language and concepts have changed markedly in the past 10 years, from *mainstreaming* to *inclusion*. The program and philosophical initiatives reflected in the Regular Education Initiative (Will, 1986) speak directly to this change.

In recent years several significant decisions have been reached by trial and appellate courts which have increased the significance of the least-restrictive-environment requirement in judging the appropriate education standard. Each has served to further interpret those sections of IDEA that bear heavily on the least restrictive environment/inclusion mandate. In *Daniel R. R. v. State Board of Education* (1989), the Fifth Circuit Court of Appeals constructed from the language of IDEA a two-part test for deciding whether a school district is in compliance with IDEA's least restrictive requirement. First, a determination must be made "whether education in the regular classroom, with the use of supplementary aids and services, can be achieved satisfactorily" (874 F. 2d. at 1048). Second, if a court determines that placement outside a regular classroom is necessary for the child's educational benefit, it must then decide "whether the school has mainstreamed the child to the maximum extent appropriate" (874 F.2d at 1048).

With *Daniel R. R.* in place the parents of Rafael Oberti sued the school district to move Rafael from a separate classroom to a regular classroom. Rafael is a Down's Syndrome child. In *Oberti v. Board of Education* (No. 92-546, 1993), the Third Circuit Court of Appeals found in favor of the Oberti family and identified three factors that should be considered in deciding whether a child can be educated satisfactorily in a regular classroom with supplementary aids and services. First, what steps has the school taken to try and include the child in a regular classroom? Second is a comparison between the educational benefits the child will receive in a regular classroom (with supplementary aids and services) and the benefits the child will receive in the segregated, special education classroom. Third, what is the possible negative effect the child's inclusion may have on the education of the other children in the regular classroom? Only after a consideration of these three questions can the question of including the child in school programs with nondisabled children to the maximum extent appropriate be considered.

The judgment of an appropriate education is then a complex and changing issue. The fundamental constitutional, legislative, and judicial requirements allow for the delineation of some general practice considerations, including:

- IEPs are created by a team (professionals and parents).
- The process followed by the team is an important legal consideration in judging the appropriateness of the school based decision.
- The content of the IEP is equally important, from the perspectives of what is stated, what is not stated, and what is missing that should be stated.
- Programming must proceed on the basis of what is articulated in the IEP.
- There must be measureable goals and objectives for each student and evaluation of a student's progress is required so that results are realized, not just services provided.
- Parental participation is absolute at every stage.
- Appeal of school district decisions is permitted, first through the administrative hearing process and second through the court. Appeals may be based on either alleged procedural violations or alleged content/substance violations.

The Family Educational Rights and Privacy Act

The Family Educational Rights and Privacy Act (FERPA, 1974, also referred to as the Buckley Amendment) was adopted by Congress at the same time it passed the original legislation providing an education for disabled students. Adopted as a result of many complaints from parents and students about record inaccessibility and inaccuracy, the law established rules regarding access and inspection, copying, and release. Many of the requirements were repeated in later legislation (e.g., IDEA). Although the law is over 20 years old, questions remain and some disagreement over the accessibility of certain records continues.

Questions focus on which records are accessible, which, if any are exempt, and whether the procedures and principles of confidentiality, privileged communication, and test security relate in any way to the records-access law. Frequently the questions focus specifically on accessibility of test protocols, and "private notes." The answer to such questions is partially found in the law's definition of a record *and* through a study of congressional intent regarding the law. An education record is defined as follows:

A. For the purposes of this section the term "education records" means, except as may be provided otherwise in subparagraph (b), those records, files, documents, and other materials which

   i. contain information directly related to a student and;

   ii. are maintained by an educational agency or institution, or by a person acting for such an agency or institution.

B. The term "education records" does not include:

   i. records of instructional, supervisory, and administrative personnel ancillary thereto which are in the sole possession of the maker thereof and which are not accessible or revealed to any other person except a substitute.

Where psychologists have questioned the right of parents to access certain records, they usually have referred to Part B. In claiming that a protocol is not an accessible record some school psychologists have claimed that a protocol is in their sole possession and that they are the exclusive maker, or that the protocol is a private note.

When the meaning of legislation is unclear the intent may be learned through a review of the congressional debate and/or accompanying statements of explanation. It is here that the intent of the law is found and in this case helps clarify the issue of accessibility of protocols. It is in the Joint Statement in Explanation of Buckley/Pell Amendment (Congressional Record at S.21488, December 13, 1974) that the intent of the definition and exception is partially clarified.

> An individual should be able to know, review, and challenge all information — with certain limited exceptions — that an institution keeps on him, particularly when the institution may make important decisions affecting his future, or may transmit such personal information to parties outside the institution. This is especially true when the individual is a minor. Parents need access to such information in order to protect the interests of their child.
>
> The amendment makes certain reasonable exceptions to the access by parents and students to school records. The private notes and other materials, such as a teacher's daily record book, created by individual school personnel (such as teachers, deans, doctors, etc.) as memory aids would not be available to parents or students, provided they are not revealed to another person, other than in the case of a substitute who performs another's duties for a temporary period.

Continuing, the statements go on to say:

> If a child has been labeled as mentally or otherwise retarded and put in a special class or school, parents would be able to review materials in the record which led to this institutional decision . . . to see whether

these materials contain inaccurate or erroneous evaluations about their child.

The Congressional intent is affirmed in *John K. and Mary K. v. Board of Education for School District 65* (1987). This Illinois appellate court decision held that raw psychological test data is part of a student's temporary record subject to disclosure. The school psychologist who had administered the Rorschach argued that the verbatim responses were raw data and not subject to disclosure. The court was not persuaded either by professional standards or by federal regulations that the psychologist cited in support of nondisclosure.

Of relevance to the question of accessibility are the requirements of PL 94-142 that provide parents the right to inspect and review their children's records collected, maintained, and used by the school in its special education decision making. It would be difficult to argue that test results are not used by psychologists in this process and therefore inaccessible. Certainly a parental challenge to placement (either at the hearing or judicial level) would result in a request to review test protocols. To refuse would be to deny parents the right to review important records on which the school's decision was based. Finally, access does not necessarily mean obtaining a copy. With respect to test protocols publishing companies have made it clear that such material is protected by copyright restrictions. So while parents or their legal representatives might have access, indiscriminate or wholesale copying is not allowed. Clearly the access-to-records requirements necessitate a delicate balance between the public right to be informed and the psychologist's responsibilities to the student and accepted professional standards.

SUMMARY

As a profession we have come to experience ongoing changes that affect our practices and procedures. The sources of change come from both within and outside the discipline. The legal influence has been pervasive and constant. As school psychologists we understand the mandates of parental participation, notice and consent, the requirement that all children with disabilities be afforded an education, and the necessity to ensure valid and reliable assessments that address educational needs. There are constitutional foundations and statutory requirements for these and other practices and any change in our practice will require adherence to these.

Many of the emerging reforms in school psychology are compatible with sound legal practice — practice that honors not only the technical requirements of the law — but the intent as well. Some examples include

- Curriculum-based assessment faces fewer problems associated with cultural differences than does norm-referenced assessment.
- Greater emphasis on classroom-based instruction responsive to the individual needs of disabled students who are educated as a matter of first course with nondisabled students invites (if not demands) integration in the least restrictive environment.
- Meaningful evaluation of short-term objectives and long-term goals increases the likelihood of achievement-oriented results and is more readily accomplished when using curriculum-based assessment.

In the end our challenges should be focused more on successful educational interventions than conformity to procedural due process. The more success we have with the former the less we will need to be concerned about the latter.

ANNOTATED BIBLIOGRAPHY

Hart, S., & Prasse, D. (Eds.). (1991). Children's rights and education. *School Psychology Review, 20,* 331–440.
This theme issue of the *School Psychology Review* provides perspectives on the historical evolution of children's rights, clarifies the significance of core rights and issues, and indicates their relevance for education and school psychology. The articles react to the United Nations Convention on the Rights of the Child and are conceptual as opposed to empirical, often surfacing themes of the dignity of children as persons.

Jacob, S., & Hartshorne, T. (1991). *Ethics and law for school psychologists.* Brandon, VT: Clinical Psychology Publishing.
The authors present a comprehensive overview of legal influences on the practice of school psychology. Coverage includes both statutory and judicial review and ethical standards. Important issues such as privacy, confidentiality, research, and consultation are all covered. The book is well organized and includes many original references to the relevant issues affecting special education and school psychology.

Keith-Spiegel, P., & Koocher, G. (1985). *Ethics in psychology: Professional standards and cases.* New York: Random House.
Excellent coverage of applied practice and ethical issues. This book uses text and cases adjudicated before various ethics committees. Comprehensive chapters are included on record keeping, assessment, therapeutic intervention, dual-role relationships, and others. Each chapter begins with a definition and thorough explanation of the topic followed by application drawing on different cases and professional standards.

Melton, G. (Ed.). (1989). *Reforming the law: Impact of child development research.* New York: Guilford.
This compilation of chapters drawing on years of child development research in a wide range of areas assesses the impact of research on children's competence in decision making. Chapters provide coverage of the broader areas of applied psychology, scientific knowledge, and judicial decision making. Drawing from a research foundation, authors provide suggestions for influencing the legal system.

Prasse, D. (1988). Licensing, school psychology and independent private practice. In T. R. Kratochwill (Ed.), *Advances in school psychology: Volume VI* (pp. 49–80). Hillsdale, NJ: Lawrence Erlbaum Associates.
This chapter provides an overview of regulation and licensing. Scope and authority of licensing is presented and coverage is given to legal and ethical considerations in professional practice. Examples of specialty licenses in school psychology are presented along with definitions of scope of practice. Emergent problems associated with delivering school psychological services in the private sector are discussed.

Best Practices in System-Level Consultation and Organizational Change

Michael J. Curtis
Stephanie A. Stollar
University of South Florida

OVERVIEW

Consider four situations seemingly quite different, but each of which might very well confront a school psychologist:

- A fifth-grade team is concerned about an increase in the number of incidents involving aggressive behavior among their students and wants to work with parents in addressing the problem.
- An elementary school wants to implement an intervention assistance program to provide more support to classroom teachers in their efforts to respond to the needs of their students.
- The Board of Education decides to establish local school improvement teams in each of the schools throughout the district.
- The Child Development Council is faced with numerous logistical problems resulting from the anticipation of a dramatic increase in enrollments in its Head Start programs.

Each of these cases represents a system-level problem. At the very least, each situation is likely, directly or indirectly, to impact the school psychologist (e.g., requests for help with incidents of aggressive behavior, participation as a member of an intervention assistance team, operational changes in the school resulting from the work of the local school improvement team, problems experienced by both teachers and children when a Head Start Center opens despite many unresolved logistical issues). On the other hand, each is a situation in which the school psychologist, through system-level consultation, could serve as a valuable resource in facilitating change at a classroom, grade, building, district, or county-wide level.

The frequency of discussions and reports of activities relating to school reform efforts all across the United States suggest a tremendous need for the involvement and support of individuals highly skilled in problem solving and in understanding and facilitating organizational change. Consequently, this may be an opportune time for school psychologists to consider expanding typical roles and functions into this new area of professional service, a service that could indirectly benefit many more students than typically can be impacted through direct services to individual students (e.g., assessment, counseling).

Although system consultation has not been among the services emphasized by many school psychologists, it is an area to which many school psychologists could bring valuable knowledge and expertise. The foundation of psychology is understanding human behavior. A special strength of school psychology is understanding human behavior, that of children as well as adults, within the context of schools and educational institutions.

BASIC CONSIDERATIONS

There are some circumstances in which a school psychologist might function in the role of a system consultant from outside the organization. In other words, he or she would be specifically employed to deliver system-level consultation. However, in most cases, the school psychologist will be an employee of the organization and system consultation will represent only one of a variety of direct and indirect services offered. To engage effectively in system-level consultation, school psychologists need to call upon three areas of expertise in addition to their foundation of knowledge regarding human behavior: (a) understanding human behavior from a social systems perspective, (b) ability to use collaborative-planning and problem-solving procedures, and (c) familiarity with principles for organizational change.

Schools as Social Systems

Although schools usually can be identified by their physical appearance, without the students, teachers, special services professionals, administrators, and other personnel who work there, they are very much like any other building. Bricks, mortar, steel beams, and glass, regardless of their configuration, do not indicate much about the character of a school; it is the people within who give it life and make the school a living social system. Thus, if 10 school buildings were exactly the same in terms of physical structure, no 2 among them would be functionally alike because of the uniqueness of the individuals who inhabit each school building.

Understanding systems. System-level intervention and organization development are founded in general systems theory. Initially, the application of systems theory was confined largely to military and industrial settings. The relevance of systems theory to the behavioral sciences did not emerge until the mid-1950s. Consideration of this theory in schools as a framework for analyzing complex organizational problems and developing solutions did not begin until the mid-1960s.

What is a system? It is important to clarify the meaning of the term *system*. Simply stated, a system is an orderly combination of parts that interact to produce a desired outcome or product. An automobile engine is an example of a system. It consists of a number of specific parts that interact to produce power and motion. However, in contrast to a living system, an automobile engine is an example of an *inert* system; that is, as long as the parts continue to function, the engine should continue to produce power in essentially the same way.

Schools are *living* systems because, as noted previously, it is people who give schools their real meaning. Technically, living systems exist on a continuum beginning with individual cells within a human being and extending all the way to the entire population of the earth. For the purposes of this chapter, however, a somewhat narrower spectrum is appropriate. For our purposes, *a system is the orderly combination of two or more individuals whose interaction is intended to produce a desired outcome.*

Consistent with this definition, a school is a system because it consists of component parts (e.g., students, teachers, school psychologists, cafeteria workers, parent volunteers, principal) that are organized in some fashion and interact for the purpose of producing a definable outcome, educated children. As is true of all systems, the school is also part of a larger system, the school district. Individual classrooms, grade-level teams of teachers, local school-improvement committees, and intervention assistance teams are also examples of systems. Each consists of component parts that interact for the purpose of attaining desired outcomes, and each exists within a larger system.

Reciprocal influence. A critical feature that differentiates a living system from an inert system is its ability to interact with and to react to its environment, both internally and externally. Because of their capacity to interact with the environment, all living systems are *open systems*. Each of the parts of a system influences all of the other parts as well as the performance of the system as a whole. A change in one part will cause change in other parts of the system. For example, if the building principal (one component of the school) is replaced by a new principal, that change is likely to effect classrooms, students, teachers, the school psychologist, cafeteria workers, and so forth. Although changes in one component of the system may tend to have more impact than do others because of the role played by that particular part (a principal versus one student), *each part*, regardless of role or size, influences the system to some degree. There also can be circumstances that significantly alter the influence normally expected by a change in one part (e.g., a tragedy involving one student that impacts everyone in the school). Similarly, changes in the larger surrounding environment (called the suprasystem) influence the system as well as the components (called subsystems within). For example, the enactment of a new district policy on discipline would influence the individual school as well as its teachers, students, and other personnel to varying degrees.

A systems perspective involves the ability to understand the reciprocal influence that the various parts of a system, the system itself, and the surrounding system or environment exert on one another. Bandura (1978) suggested viewing the individual child within a systems framework. From the systems or ecological perspective, the child is one element in a larger environment. Personal characteristics, behavior, and forces within the environment are all interrelated and influence each other. The child influences and is influenced by various forces in the system of which she or he is a part.

The capacity of the system to solve problems. One of the ways in which systems differ is the extent of their openness to environmental influences. Systems deemed healthy, based on their identified goals screen environmental information, accepting what is important, rejecting what is not, and responding in a manner appropriate for the information received. In other words, healthy systems demonstrate the capacity to analyze problems and to solve them in a manner that facilitates the attainment of their goals.

Of course, some systems lack the capacity to solve problems effectively. In some cases, they are not sufficiently open to accept important information. Or they may have been open at an earlier time, but because they did not have the ability to solve problems confronting them, they became closed (somewhat like the ostrich with its head in the sand). The inability to interact with influential forces, internally as well as externally, creates tremendous tension in closed systems. If the tension reaches a high enough level, a crisis occurs which causes some type of change in the system.

Rigidity Elementary School, Anywhere, U.S.A., offers one illustration of a closed system. An increasing number of discipline problems are occurring on school buses transporting students to and from the school. As a result, several parents have called the school to express their concerns. Initially, the principal tells the parents that these are isolated incidents and that such problems rarely occur. As the problems continue to increase, the principal has the receptionist screen his calls, telling parents that he is in a meeting and will return their calls later. However, the calls are never returned. Angry parents show up at the school, asking to see the principal, but he is unavailable. Frustrated and fearful for their children, the parents show up and voice their anger at a meeting of the district board of education. Eventually, the principal is forced to respond to the parental concerns or is replaced.

On the other hand, some systems are too open and are unable to screen environmental forces. They essentially accept all input and try to respond to everything, often with the same level of intensity. They are overwhelmed and operate in a constant state of crisis. Everything must be done immediately! Crisis Elementary School, Elsewhere, U.S.A., serves as an example of this type of system. In this case, every time a parent calls the school to express a concern, the principal responds by writing a memorandum to the entire staff or creating a new policy that impacts the entire school. The result is that the school is in a constant state of change. In such systems, because there is a lack of stability and continuity, it is exceedingly difficult to set goals, make plans to attain them, and monitor progress.

The primary goal of system-level consultation is to increase the problem-solving capacity of the system so that it can deal with all problems more effectively. In this way, system-level consultation is exactly like one-to-one consultation. While the immediate objective in one-to-one consultation is to help the consultee (the person requesting assistance) solve the problem causing the concern, the primary objective is to help that person become more effective in solving similar problems in the future In system-level consultation, the system is the consultee. While the immediate goal is to help the system solve a specific problem, the primary goal is to facilitate the development of the system as an effective problem solver. In both cases, although involvement in consultation is likely to result in improved problem solving for the consultee(s), direct consultee training in problem-solving methods will result in greater and more immediate skill development.

Collaborative Planning and Problem Solving

Collaboration serves as the foundation for system-level consultation. In simple terms, collaboration means working together to achieve a common objective. *For the purpose of consultation, whether one-to-one or system level, collaboration means two or more people working together, using systematic planning and problem-solving procedures, to achieve desired outcomes.*

The principles of collaborative planning and problem solving that apply to individual consultation are directly relevant to system-level consultation as well. In fact, collaborative one-to-one consultation and system level consultation are directly parallel in almost every respect. Although we will not discuss one-to-one consultation skills in depth here, it would be helpful to note very briefly some of the fundamental characteristics of effective consultation.

Interpersonal relationships. Effective consultation is based on mutual respect, trust, and coordinate power status among the participants. The role of the system consultant is to facilitate the efforts of the group to achieve the goals that *the group* has decided upon, in a manner that *the group* chooses. Effective communication skills are essential for a consultant. The ability to listen, ask open-ended questions, paraphrase, and summarize and synthesize information, all within a nonjudgmental climate, are especially important. While these skills are important for all consultants, they take on added significance when attempting to facilitate change from *within* the system. Group members often are not very tolerant of a member whose behaviors tend to alter the coordinate power status among members (e.g., giving advice or feedback to the group or to individual members).

Planning and problem-solving skills. It is essential to remember that consultation is a problem-solving process and that attention to *both* interpersonal relationship skills *and* problem-solving procedures are critical in determining success. Curtis and Van Wagener (1988) demonstrated that despite highly effective interpersonal skills, consultation was not effective in resolving student-related concerns when problem-solving procedures were not employed. Effectiveness in each area is necessary but insufficient by itself.

Fundamentally, planning and problem-solving procedures are very similar, with the major difference being one of direction, that is, desired outcome. Whereas planning is intended to achieve a desirable goal, problem solving is intended to alleviate an undesirable condition.

There are literally hundreds of articles and other works in which authors have discussed planning and/or problem solving. Many models have been proposed that apply such procedures in different ways and incorporate varying numbers of steps or stages. Although the number of steps may vary, most models reflect, implicitly if not explicitly, the inclusion of four major stages:

1. Problem/Situation Analysis.

2. Goal Identification
3. Strategy Development and Implementation.
4. Evaluation.

Regardless of the model chosen, effective consultation must include all four of these stages. However, it also should be noted that although such models typically describe a specific sequence of stages, actual problem solving during individual consultation often does not proceed in such a mechanical, lockstep manner. Rather, it is common for there to be movement back and forth among the stages. Nevertheless, the general sequence of stages typically should occur as described and *all* stages must be included. For a comprehensive review of the consultation literature and a discussion of the core characteristics of different consultation models (including interpersonal relationships) and problem solving, the reader is referred to Gutkin and Curtis (1990).

Principles for Organizational Change

Applying system-level analysis and organization development to schools received little if any attention until the mid-1960s so the area remains relatively new. Nevertheless, a considerable amount of organizational change research and conceptual literature regarding other social systems has been published. This work, when combined with the research and conceptual literature generated specific to educational settings, has yielded a useful knowledge base to guide system-level consultation in schools. Fullan, Miles, and Taylor (1980) have provided an excellent comprehensive review and synthesis of the organization development literature available up to that time. Although other relevant work has been published since then, the review by these authors still probably represents the best single resource on the state of the art regarding organization development in schools.

BEST PRACTICES

Best practices in system-level consultation can be illustrated through an examination of key concepts and practices addressed in the organizational change literature. Furthermore, it is important to remember throughout the following discussion that system-level consultation is a problem-solving process and, therefore, directly parallels the steps of individual problem solving. Key concepts and principles for organizational change through systems consultation will be identified and discussed.

Planning for Change

A definition of organization development provides fundamental principles to guide the practice of system consultation. Although a number of definitions have been suggested, for our purposes, *organization development is the planned and sustained effort to bring about system-level improvement through self-analytic and problem-solving methods.* System-level change must be planned and pursued in a systematic manner over time. It does not just happen. Furthermore, it is not an event or activity, but an ongoing process. The definition presented above also emphasizes the critical point discussed earlier; that is, the primary goal of system consultation is for the system to become more effective in solving all problems. Solving a specific, precipitating problem should be considered only a short-term goal. However, it typically is the precipitating problem that provides an opportunity to engage in a longer, sustained effort for system-level change. In this way, system consultation parallels individual consultation. A specific concern causes the consultee to seek assistance. But the resultant involvement in consultation is intended to increase the general problem-solving skills of the consultee as well as to address the precipitating concern.

The Uniqueness of Each System

The same intervention methods would not be employed to address different concerns relating to different students. The intervention would have to fit the specific problem in each situation. Yet, in system consultation, there sometimes seems to be a tendency to use the same change strategies, regardless of the specific characteristics and needs of different systems.

System consultation is built upon careful analysis of the organization and of the resulting plan that is designed to address the unique needs and characteristics of a particular system. Two types of procedures that are useful at this stage include *diagnostic evaluation* and *input evaluation*. Diagnostic evaluation is helpful for identifying the needs of the system through multiple sources. It might be conceptualized as a multifactored evaluation at the system level. Formal techniques such as surveys and questionnaires may be combined with informal measures such as interviews and observations to provide a complete understanding of the organization. Needs assessments are particularly useful not only for gathering information about the organization but for involving all members of the system in the change process (Curtis & Metz, 1986).

Once the needs of the system have been clearly identified, available resources that may be relevant to addressing those needs are examined through input evaluation. The skills and resources of the staff, support of parents and district personnel, and financial resources are some of the factors to be considered. Focusing on problems can sometimes make it easy to overlook the importance of acknowledging and building upon the existing strengths, resources, and successes of the system. Attitudinal factors may be just as important as tangible resources. The planning stage of system-level consultation is directly parallel to the intent of the problem analysis stage of the problem-solving process used in individual consultation. A thorough understanding of all relevant factors, both negative and positive, must be developed before moving forward.

Commitment of Key Personnel

Because successful change requires a large investment of staff time and effort, voluntary participation is desired. In addition, the high level of involvement necessitates the commitment of key personnel. At the very least, such persons cannot be obstacles if the change effort is to succeed.

Gatekeepers. It is essential to identify all *gatekeepers* before any aspect of the change process, including diagnostic evaluation, is initiated. The role of the gatekeeper is characterized by decision-making power, ability to distribute resources, and authority within the system. Gatekeepers must not only give sanction for the change process but, optimally, provide support and fully participate with all other members of the system. Sometimes, just the nonparticipation of the gatekeeper can be a negative factor warranting consideration. The role of gatekeeper is most commonly held by personnel such as the principal or superintendent. However, staff in less obviously powerful positions, such as the school secretary or specific teachers, can function as gatekeepers and be influential in determining the success or failure of change efforts.

Involvement of all stakeholders. In addition to securing the commitment of gatekeepers, those involved in organizational change must see that all *stakeholders* in the system participate in every stage of the change process. This is a fundamental principle for oganizational change. Stakeholders are all members of the system who will be impacted by the change. Decisions about system-level change in schools are often made at the administration level. Failure to involve important stakeholders, such as classroom teachers, will negatively impact the organizational change effort.

Many efforts to implement intervention assistance programs in schools have violated this fundamental rule. Typically, the discussions, planning, and even implementation have involved seemingly everyone *but* classroom teachers. Principals, special education personnel, school psychologists, and other related services professionals then "inform" teachers about the new procedures. Confusion and frustration result when teachers do not participate regardless of the good intentions of the change agents. Common sense suggests that classroom teachers are *the* primary stakeholders among a school's professional staff who will be impacted by the implementation of intervention assistance programs. They should be meaningfully involved in every aspect of such change efforts, beginning with initial discussions regarding *potential* change and continuing through implementation.

Demonstrating change strategies. Because an organizational change effort must be planned and sustained over time, it is important that not only key personnel, but all stakeholders, have a realistic understanding of what may be involved. Otherwise, the absence of immediate change (an unrealistic goal to begin with) could lead to the loss of commitment and investment in the process. Therefore, it may be helpful to demonstrate change methods so the group can gain familiarity as well as experience success in addressing real concerns. Curtis (1982) suggested that teaching group problem-solving techniques is helpful in securing the commitment of the school staff. This activity could involve having the participants identify real concerns and establish goals for change. Then, group problem-solving skills are used to develop strategies to address the concerns. This exercise serves to teach the problem-solving skills necessary for planning change as well as confirms the commitment of the staff to the goals for change. Curtis and Metz (1986) provide a case study in system-level change that employs this type of strategy.

Goal Identification

Based on the diagnostic evaluation and input evaluations, specific desirable outcomes should be identified. It is critical that these goals reflect information derived during the problem-analysis procedures. These goals will determine the types of system-level intervention considered, and specifically those chosen for implementation. It is at this stage that groups often discover that they have identified several different, although related, goals. Refinement of goals and the selection of one goal at a time to pursue through specific change strategies will enhance the likelihood that the group will be successful in their efforts.

It also is important to *establish realistic, concrete, system-level goals*, especially during the early stages of an organizational change effort. When seeking organizational change, planners can get lost in an "all-or-nothing" view of the system. The consultant needs to break larger goals down into more reasonable steps by which change can be measured. Even a small initial change has the potential to create a ripple effect that leads to more significant change later. For example, one school psychologist began by regularly scheduling only 15 minutes each week to talk with the building principal about building-level issues. After a few weeks of such talks, an interesting journal article related to one of the issues discussed would occasionally be given to the principal. Over time, the school psychologist came to be viewed by the principal as a source of information and expertise regarding a broader range of issues, particularly as they pertained to organizational concerns.

Strategy Development and Implementation

System-level consultation involves ongoing activities to address long-term goals. Intervention is not conceptualized as a single event. Therefore, it is helpful to have a staff member who will serve as facilitator of the change process. Although school psychologists may be well suited for this role, the itinerant nature of many school psychology assignments may preclude involvement in the ongoing monitoring of change.

The overall plan for change may involve intervention methods which target the cognitive, affective, and/or structural components of the organization. Interventions that address cognitive aspects would include instructional activities such as training staff in new technology or practice. Affective interventions are those that address the interpersonal relationships among the staff. Examples include training in communication and effective listening skills. Structural interventions focus on the way the organization is put together and its relationship to the various sub- and suprasystems. Because these components are somewhat interrelated, system-level intervention plans that address all three may be most effective. The intervention activities should be carefully selected to achieve aspects of the overall goal of the system.

Teaching Planning and Problem-Solving Procedures

As noted previously, the development of problem-solving skills by system members is the primary goal of system-level consultation. The most effective method for achieving this goal is through direct instruction, practice, and follow-up. Therefore, the consultant should provide training to as many of the major stakeholders in the system as possible. The effectiveness of the system will increase as the proportion of its members who are effective problem solvers increases.

It may be necessary to begin by training only a few members; however, providing all members with training in problem-solving skills should still be maintained as an eventual goal. For example, in working at the building level, a school psychologist may begin by training a specific group such as the local school improvement team. Once the group has been trained, had an opportunity to practice using collaborative planning and problem-solving procedures, and then refined their use of such methods through feedback, discussion, and perhaps further training, they can become a vehicle for planning training for the remainder of the staff. However, improving the problem-solving skills of any members of the system represents progress, even if training the entire staff is not possible. Any improvement should be recognized as a positive outcome of system-change efforts.

Although many different approaches to problem solving might be used, the model described in the next section has been used by this chapter's authors to train a wide range of individuals and groups in a variety of settings, including schools, agencies, and professional organizations. Each of the steps is explained briefly. Then an example is provided based on the actual work of a school-based intervention assistance team.

A Model for Collaborative Planning and Problem Solving

The effectiveness of this model is dependent on conscientious adherence to following the steps described in sequential order and thoroughly completing one step before moving on to the next. For ease of presentation, each step is explained in terms of *problem-solving* procedures. However, the same steps may be used to achieve goals identified for the purpose of *planning*.

1. *Describe the problem or concern as concretely and as specifically as possible. Once the problem has been defined, identify the desired outcome of your problem-solving efforts, again using concrete, descriptive terms.*

Often, what initially is thought to be a problem, once analyzed, is recognized to be several distinct, although perhaps related problems. Record all problems identified. Although all of them may not be dealt with during a particular session, once recorded, they can be addressed during subsequent sessions. Identify the specific problem that will be addressed *first*. Then, define the desired outcome that would result from resolution of only that specific problem. It is essential that all members of the problem-solving team have the same understanding of the problem to be addressed and of the desired outcome.

2. *Analyze the specific problem chosen in terms of factors that might help in addressing it (resources)* and *factors that serve as obstacles to its resolution.*

Using a "brainstorming" process, all members of the group participate in generating a list of resources and obstacles. The use of only concise statements should be encouraged. It is essential that ideas are not discussed, evaluated, or even clarified at this point. The intent is to produce as much information as possible by involving all members of the group in a free flow of ideas. Record only enough about each idea to allow clarification by its originator after brainstorming is completed. This should be recognized as an "idea" stage. There have been no decisions made regarding actions to be carried out.

3. *Select* one *obstacle that is significant in terms of its hindrance to resolving the specific problem identified in Step 1.*

The obstacle selected should be viewed as the first obstacle to be addressed, not as the only one. It is best to avoid trying to identify the most important obstacle to reduce concerns that may be associated with ownership according to who generated specific ideas. Other important obstacles can be noted for future attention.

4. *Focusing only on the one obstacle selected in Step 3, brainstorm resources and activities that might be used to reduce or eliminate that obstacle.*

The list of resources identified in Step 2 serve only as a stimulus for the generation of ideas. Again, because a brainstorming process is being used, the intent is to generate and record as many ideas as possible. Specific ideas can be clarified after brainstorming is complete. Remind participants that this is only an *idea* stage and that no decisions have been made regarding actual action plans.

5. *Design a concrete plan of action that reflects accountability for completion (i.e., who, what, when).*

If possible, several action plans should be developed to address the same obstacle. In that way, if one plan is not carried out or does not attain the desired results, the identified obstacle still may be reduced or eliminated through other actions. Each plan should clearly identify *who* (by name) is responsible for carrying out *which* specific activity (include as much detail as possible) by *what* date. Avoid stating any aspect of a plan in general terms; the greater the detail provided in a plan, the greater the likelihood that it will be carried out as intended and on time. Sometimes, it is desirable to try out an action plan on a limited scale before proceeding with full implementation.

6. *Establish a procedure for follow-up and review.*

Consider interim reporting dates and procedures to check on the progress of an action plan, rather than waiting until the deadline for its conclusion. This stage also is used to evaluate the effectiveness of action plans and for modifying them or even recycling to an earlier stage in the process.

Example of the Six-Step Problem-Solving Model

To clarify the problem-solving process within the limits of the space available, the following example includes only selected entries for some steps.

Original concern: The teachers are not using the Intervention Assistance Team as a means for helping them respond to the special needs of their students.

Statement of problem/concern: Many of the staff are unaware of the benefits they can receive from intervention assistance.

Resources:

- Some staff have used the process and realized benefits.
- Resource people have worked with other schools where process is working well.

Obstacles:

- Intervention assistance is viewed as a barrier to testing.
- We haven't communicated very effectively with our staff about process and results.

Obstacle selected: We haven't communicated very effectively with our staff about the intervention assistance process and the results.

Brainstormed ideas:

- Conduct an in-service on the benefits.
- Report regularly during staff meetings.
- Disseminate written reports on process and results.

Action Plan 1: Sue, Anne, and Mr. Allen will make a presentation at the staff meeting on March 10th about the process and how it is intended to be a resource for teachers.

Action Plan 2: Jim will contact several teachers who have used the process and ask if they will report during the March 10th staff meeting on the benefits they experienced. He will contact them by March 3rd.

Action Plan 3: Mr. Allen will contact Jan Smith, a school psychologist who works in several schools, to ask if she will also make a brief presentation during the staff meeting regarding the benefits being realized in some other buildings. He will contact her by March 3rd.

Follow-up: The intervention assistance team will meet March 3rd at 3:00 p.m. to review the plans for the in-service program and to make any final arrangements.

Evaluation

Measuring progress can be achieved on two levels: (a) progress toward the objectives of specific intervention activities and (b) progress toward the long-term goal. As with individual consultation, frequent evaluation is essential for determining progress and identifying the need for adjustments to the plan.

SUMMARY

Many opportunities exist for school psychologists to expand their role to include indirect service to students through system-level consultation. By building on current competencies, school psychologists can increase participation in system-level

change efforts by viewing behavior from a systems perspective, using collaborative-planning and problem-solving procedures, and becoming familiar with principles for organizational change. The fundamental components and goals of individual consultation are directly parallel to system-level consultation. Any planned change effort, no matter how small, can be an important step toward improved services for students.

ANNOTATED BIBLIOGRAPHY

Fullan, M., Miles, M. B., & Taylor, G. (1980). Organization development in schools: The state of the art. *Review of Educational Research, 50*, 121–183.
Although somewhat dated, this article provides the most comprehensive theoretical and empirical review of the use of organization development (OD) in schools. The authors present the defining characteristics of OD in general and as applied to education, the various models of OD in practice, an assessment of the outcomes of OD, and suggestions for future applications.

Gutkin, T. B., & Curtis, M. J. (1990). School-based consultation: Theory, techniques, and research. In T. B. Gutkin & C. R. Reynolds (Eds.), *The handbook of school psychology* (2nd ed., pp. 577–613). New York: Wiley.
An excellent resource for information on the components of individual consultation. This chapter provides a comprehensive review of the core characteristics of school-based consultation. The steps of problem solving are outlined within the framework of a systems orientation. Also reviewed are the major approaches to school-based consultation including the ecological and mental health models. Critical research and professional practice agendas are presented for closing the gap between real and ideal roles for school psychologists.

Schmuck, R. A., & Runkel, P. J. (1985). *The Handbook of Organization Development in Schools.* Palo Alto, CA: Mayfield Publishing Co.
The third edition of *The Handbook* reflects 15 years of collaboration and research on organization development at the University of Oregon. The book was designed to be used as both a college text and as a resource for practitioners. Each chapter is written so that it can be read and understood independently of the rest of the book. The chapters are grouped by major themes which cover theory, communication and problem solving, decision making and conflict, and diagnosis and evaluation. Ideas, exercises, and procedures are offered for each section.

Snapp, M., Hickman, J. A., & Conoley, J. C. (1990). Systems interventions in school settings: Case studies. In T. B. Gutkin & C. R. Reynolds (Eds.), *The handbook of school psychology* (2nd ed., pp. 920–934). New York: Wiley.
This chapter provides nine case studies that illustrate systems-level interventions by school psychologists. Examples of school psychologists expanding their role as consultants, both internal and external to the school system, are provided. The idea that change at any level in one subsystem affects change in other interrelated subsystems is emphasized.

Trends in the History of School Psychology in the United States

Thomas K. Fagan
University of Memphis

OVERVIEW

This chapter is not a chronological or topical treatise about the history of school psychology, such as those appearing in Fagan (1990), French (1990), and Fagan and Wise (1994). Instead, it expands upon previous work by providing brief descriptions of trends in selected aspects of the history of school psychology over the past century. Trends in practice settings, roles and functions, and other areas of the field are changing. We may be entering a period in which many aspects of school psychology will be revised; this period of revision would follow earlier periods of uncertain identity, unprecedented growth, and stabilization. Historical trend analyses, revealing the stability of some professional developments and the changeability of others, help us understand questions about our present by reflecting on our past. For example, is the organizational growth since 1970 unprecedented? Is the literature of school psychology more diverse than in earlier times? Is the practice of school psychology different than it was 50 years ago? Have school psychologists always had children as their primary clients? These and other questions will be addressed in this chapter. The discussion is not intended to be comprehensive, but rather to provide an overview of some important trends in school psychology. Certain trends are discussed in detail because they have not been surveyed in other sources, while some are treated only briefly because they have been discussed elsewhere.

Number of School Psychologists

The earliest survey of psychological practitioners serving school settings was undertaken in1913, and identified only 115 persons. Growth in the number of school psychologists was gradual but persistent, and by 1950 there were about 1,000. The post-World War II baby boom, with its growth in school attendance, and the enactment of comprehensive special education laws entailing mandatory psychological services were dominant forces affecting the rapid growth of practitioners observed after 1950. By 1970 the field had about 5,000 practitioners; current estimates range from 22,000 to 25,000. In recent years, growth can also be attributed to the expansion of settings in which school psychological services are delivered. Estimates of the size of the work force usually include trainers and state government personnel as well as practitioners. However, trainers comprise a very small proportion of the work force, perhaps three to five percent; and government personnel such as state consultants account for about .3%. The size of the work force at different times is estimated as follows:

1920	200	1970	5,000
1940	500	1975	8,000
1950	1,000	1980	10,000
1960	3,000	1985	15,000
1965	4,000	1990	22,000

For all the studies and estimates, no reliable count of the number of school psychologists has ever been accomplished. Even the term "school psychologist" has eluded consistent definition — adding to problems of whom to count and with whom past and future comparisons should be made. Recent estimates are probably more accurate than early estimates, but exactitude is still lacking, with estimates off by perhaps 10% or more. Despite problems of accuracy, the trend in upward growth nevertheless has been significant. Continued growth is expected in the future, but not of the magnitude witnessed in the past 25 years. The number of school psychologists will probably not exceed 30,000 to 35,000 in the coming 20 years.

Gender Trends

Public school teaching was a male-dominated field early in the history of American education, but has been dominated by women throughout the twentieth century, ranging from 86% (1919–1920) to approximately 65% in recent years. Throughout this century school psychologists have been drawn in large numbers from the ranks of teachers. Even in recent years many school psychologists hold teaching credentials and have teaching experience. Although early survey data are not available, it is known that several women were among the early practitioners of school psychology (e.g., Norma Cutts, Helen Thompson Woolley, Leta Hollingworth); that women held several prominent district-level administrative positions in school psychology (e.g., in Cleveland, Chicago, Cincinnati, Detroit), state department of education positions (e.g., Wisconsin, New York), and university positions (e.g., Columbia, Purdue); and comprised one-fourth of the Thayer Conference participants (French, 1988). Division 16–APA data indicate that women accounted for more than 60% of the membership and elected leadership in 1949, and 54% of its 600 members in 1956–57. The figures appear to have declined to less than 50% by the 1960s, a period when men gained proportionally in leadership positions (Hagin, 1993). A more representative survey by Farling and Hoedt (1971) found an overall female representation of 40%, including 35% of the APA member respondents and 47% of the NASP member respondents. A 1976 survey reported female representation of 45% (Ramage, 1979). By 1982 a NASP survey found women comprising 58% of the membership, and just three years later this had grown to 61% of the membership. Surveys in the early 1990s place the membership representation of women at 65%.

Given the representativeness among school psychologists of NASP's membership, the data suggest a substantial feminization of the field in recent years. It is probable that the proportion of women in school psychology has varied across the century, from perhaps 30% at some point early in the century to half or more during the period 1940–1960, perhaps experiencing a brief proportional decline in the 1960s and 1970s, and then rising to its present high of about 60–65%.

Female representation has varied by the types of positions held. For example, female representation is highest among practitioners (65%), while among trainers it is 30% (Reschly & Wilson, 1992). Women's representation on the Executive Board of NASP has improved from one-third to two-thirds during the period 1970–1993. A less discernible trend appears in the data for Division 16 elected leadership, although women held half or more of the positions on several occasions in the past twenty years (Fagan, 1993b). Although regional variations likely exist, there are probably few states where men are in the majority. Despite women's proportional advantage, a woman has never been appointed to the editorship of a school psychology journal, though several have served in associate editorship positions.

The feminization of school psychology is among the more predictable and significant influences on the field for the next two decades. The proportion of women in school psychology may rise to as high as 75%. While men more often have held leadership positions in the past twenty years, the trend will change dramatically at all levels, including state and national associations, academia, editorships, and state education agencies. The trend could be attenuated by recruiting more men into the field and/or by men continuing to be successful in obtaining leadership roles. With increased female presence in the leadership, the future of school psychology will be influenced by their efforts even more than in the past.

Service Ratios

The ratio of school psychologists to children served — the service ratio — has been reported many times in our history. The ratio has improved from 1:60,000 in 1934, to 1:36,000 in 1950, to 1:10,500 in 1966, to 1:4,800 in 1974, to 1:2,100 in 1986 (Fagan, 1988). In large and urban school districts the median ratio has improved from 1:18,500 in 1950, to 1:9,000 in 1966, to 1:2,000 in 1991 (Fagan & Schicke, in press). These figures are consistent with a recent report that the ratio for rural school psychologists (1:2,184) was not significantly different from that of urban (1:1,931) or suburban (1:1,892) school psychologists. Practitioners in combined settings (e.g., rural and urban) had significantly worse ratios (1:2,283) (Reschly & Connolly, 1990). The trend throughout the century, then, has been to improve ratios in various settings. Gradual improvements are anticipated for the future, but the 1992 NASP recommended ratio of 1:1,000 will remain an elusive goal.

Practice Settings

School psychologists have worked in several settings throughout history, although their primary identification has been with public and private schools. In the early decades of practice (1890–1920) they also worked in clinics and research bureaus affiliated with charitable agencies, juvenile courts, colleges and universities, and medical settings. Data by setting do not exist, but it is possible that nonschool-setting practitioners outnumbered school-based practitioners in the early years. Prominent early "school psychologists" such as Lightner Witmer and Arnold Gesell worked in the schools but from external agencies. This pattern probably changed in the 1920s. Founded in 1945, Division 16–APA (School Psychology) was originally intended for school-based practitioners, not practitioners in other settings. The Division's restrictiveness reflected a conceptualization of school psychology as applied clinical and/or educational psychology, with the school being the primary applied setting. A 1960 Division 16–APA survey found that among 233 respondents, 12 (5%) were from private schools, 11 (5%) from state school systems, 42(18%) from county school systems, and 168 (72%) from city schools (Results of Questionnaire, 1960). Setting expansion has been more noticeable since 1980, following a rapid growth of practitioners and increased interest in nonschool and independent practice. The shifting interest appears related to opportunities encouraged by PL 94–142 (e.g., second opinion evaluations), the rapid growth of third-party insurance reimbursements for psychologists, the success of other psychologists in the private sector, increased numbers of school psychologists holding the doctoral degree, and a general maturing of the field of school psychology. Recent survey data indicate the following percentage distribution of employment settings for school psychologists: public school settings (86%), private practice (4%), one percent each in hospital, college or university, institutional/residential, and clinic, and five percent in "other" settings (Reschly & Wilson, 1992).

Throughout our history we have maintained school psychology's identity with school settings despite gradual increases in nonschool practice. What does the future hold? There will be an increase in both the number of practice settings and the percentage of school psychologists serving nonschool settings. Postsecondary educational setting practice will be more available, as will agency and private practice. The expansion of practice settings depends on the growth in the percentage of practitioners holding the doctoral degree.

Clientele

The issue of clienthood is complex, but most agree that children and their parents or guardians are the primary clients of school psychologists. School psychologists came into practice in order to directly serve children while working less directly with their teachers and parents. This primary client relationship with school-aged children has been maintained throughout our history. Surveys of practice, research studies on assessment and intervention, and other descriptive reports consistently reveal that school-age children have been the most common clients of school psychologists. However, growing provision of consultation will increase the extent to which teachers and parents are the primary service recipients and clients. School-age children will continue to be the most common direct service recipients, as well as the primary target of indirect services delivered through other recipients. Although the definition of "school-age" has expanded in recent decades to include ages 3 to 21, some school psychologists provide services to persons outside this age range.

Practitioner Salaries

Salary data are practically nonexistent for the first half of the twentieth century. Nevertheless, some trends can be inferred from archival sources, from limited surveys conducted by state and national associations between 1940 and 1970, and from more comprehensive recent surveys. Early salaries can be inferred from the salaries of positions held by selected practitioners. For example, when the Chicago Public School's Department of Scientific Pedagogy and Child Study was founded in 1899, its Director was paid $2,000/year and his assistant was paid $100/month ($1,200/year) (Slater, 1980). Between 1915 and 1919, Arnold Gesell was paid $2,000 for his half-time, nine-month position with the State of Connecticut and he was reimbursed for travel, meals, postage, and telephone expenses. Finally, archival sources reveal that Gertrude Hildreth was paid $1,850 for her full-time, nine-month position in "mental testing" with the Okmulgee, Oklahoma, public schools in 1921. I suspect that the range of salaries in the period 1890–1930 was from $1,000 to $4,000 for full-time practitioners, and that a typical figure was probably $2,000 or less. Among the earliest known surveys is the 1939 State of New York survey (based only on the eight districts having a salary schedule), which found that "the range reported was from $1,400 to $4,000 – the median being about $1,600 to $2,800" (Cornell, 1942, p. 25).

The 1954 Thayer Conference survey identified an overall salary range of $3,000 to $15,000, with minimum salaries ranging from $3,000 to $4,600 and maximum salaries ranging from $3,600 to $15,000. Benefits and transportation allowances were mentioned (Cutts, 1955). A 1960 Division 16–APA survey (N = 67) revealed a median salary in the range of $7,000 to $7,999. More than half (55%) were paid $7,000 to $8,999. One-third to one-half of all respondents were given full expenses and time for attending professional growth meetings, and an additional one-third received partial expenses (Results of Questionnaire, 1960).

A reworking of Farling and Hoedt's (1971) survey data yielded a median salary in the range of $12,000 to $14,999.[1] Regional data suggested higher salaries in the Northeast and West than in the Midwest and South (p. 75). The overall upper salary range was significantly greater than in the 1960 Division 16 survey, with 84% reporting salaries of $10,000 or more compared to only 8% in the earlier survey. A 1976 survey of Division 16–APA and NASP members revealed the median salary to be in the range of $16,000 to $18,999 (Ramage, 1979).

Surveys of the NASP membership reported in its 1982 and 1985 membership directories found the median salary in the range of $22,000 to $24,000 and $25,000 to $27,000, respectively. An independent survey of practitioners (Smith, 1984) revealed a median salary range of $20,000 to $24,999. A 1990 survey of a random sample of NASP members (N = 1,781) indicated that the median salary was in the range of $35,001 to $40,000 (Graden & Curtis, 1991). Reschly and Wilson (1992) reported a median income of $35,800 for practitioners and $44,500 for academicians, but the academicians had a median age six years older.

Salaries have increased sharply in the past 30 years following small but persistent increases in the previous 50 years. The large recent increases are reflected in the 1990 data, which suggest that 40% of NASP members had salaries of $40,000 or above compared to just 8% five years earlier. Sampling methods and the effect of rapid membership increases associated with NASP's system of national certification might partially explain discrepancies in surveys from 1985 to present. Additionally, recession has slowed the rate of salary growth since the late 1980s.

Salaries by gender have not been reported, though a survey by Hall (1949) mentioned that one city had a differential between the salaries paid men and women psychologists; Smith's (1984) data suggest higher salaries for males, but this may have been a result of slightly greater levels of experience and degree attainment (see Table 2, p. 801). Teacher salary schedules, with some adjustments for psychological personnel, were reported in early and more recent surveys. No doubt, benefits also have improved in recent decades in comparison to the first half of the century.

Preparation Programs

The earliest programs were designed to prepare "clinical" psychologists to provide services in the schools. The programs were not titled specifically "school psychology" until the 1920s, when the first so-titled program was established at New York University. The second formal program appears to be the doctoral program founded at Pennsylvania State University in the late 1930s. By the time of the 1954 Thayer Conference there were 18 programs, including five at the doctoral level (Cutts, 1955). Institutions offering training in school psychology grew from 28 in 1954, to 79 in 1964, to 147 in 1974, to 211 in 1984 (Fagan, 1986b). The 1989 edition of the NASP training program directory identified 231 institutions, while the most recent edition identifies 233 program institutions (see appendix on training programs in this book). A leveling of growth in the number of training program institutions has occurred since the early 1980s. Future growth in the number of participating institutions will remain modest. The number is unlikely to exceed 250; and conceivably will decrease. The most predictable increase is in the number of institutions offering a doctoral program in school psychology.

Characteristics of Preparation

In the early part of the century, school psychology programs were oriented toward clinical psychology, educational psychology, or a combination thereof. Even the earliest training programs created specifically for school psychologists tended to take these orientations. Perhaps the earliest unambiguous joint orientation of educational and clinical psychology was the University of Illinois program, founded in 1951. Programs have been developed in both education and psychology administrative units with few apparent differences (Fagan, 1990; Reschly & McMaster-Byer, 1991).

The content of training programs was largely unregulated until the 1960s, in what might be called a long period of "diversity of necessity" in which training emerged from programs designed for a variety of educational and psychological personnel. Many of the programs established in that era combined traditional core psychology or core education courses with specialty training, including psychoeducational evaluation but with limited emphasis on interventions. With the establishment of APA and NCATE/NASP accreditation, the profession entered a period of "restriction for identity" in which very specific standards for preparation were developed to give school psychology training its own identity. Accrediting and credentialing standards also have brought about broader and more specific content in programs. The standards have significantly raised the expectations for entry-level training and have broadened preparation to include various types of assessment and intervention. The current entry-level expectation of the specialist degree or its equivalent is more than twice the expectation published in the original NASP training guidelines of the early 1970s. However, in raising the expectations to meet job demands and establish a separate training identity in school psychology, nondoctoral programs have been forced to become highly prescriptive. Doctoral programs have tended to follow the broader scientist-practitioner or professional models of preparation.

The past several decades have seen an improved balance of psychology and education-related content. Very noticeable changes have been the expansion of field experience requirements, including practica and internships, and the infusion of faculty specifically prepared as school psychologists. While a sharp increase in training standards is not expected for several years, the upward trend will continue. This may appear first at the doctoral level, where national forces are driving accrediting and credentialing toward the postdoctoral level. The nondoctoral standards will likely remain much the same for the coming decade. We should encourage a future of "diversity for maturity," where many forms of preparation will be available in order to better prepare persons for practice in a future of increasing diversity of settings and clients.

Credentialing

Although the New York City Board of Education had provisions for examining and approving school psychological personnel in the 1920s, the earliest state education agency credentials for school psychologists were granted by New York and Pennsylvania in the mid-1930s. Licensing for nonschool practice by state boards of examiners in psychology was initiated in 1945 (Connecticut). By 1960, 15 states licensed psychologists, and all states did so by 1977 (Missouri was the final state). State board of education certification was available in at least 7 states by 1946, 11 states by 1949, 20 states and the District of Columbia by the time of the Thayer Conference, 24 states (including DC) by 1960, 37 states by 1965, 42 states (including DC) by 1973, and all states (including DC) by 1977 (Brown, Horn, & Lindstrom, 1980; Pryzwansky, 1993). A historical analysis of specific changes in credentialing requirements over the past 60 years has not been undertaken and is beyond the scope of this chapter. However, a discernible trend has appeared requiring greater amounts of graduate education and supervised field experiences, and program approval or accreditation. Teaching credentials and/or experience were not required in the original certification in New York and Pennsylvania, and such requirements have declined from 12 of the 20 states certifying school psychologists at the time of the Thayer Conference (1954) to only a few states at present.

Literature

Until the appearance of the first issue of the *Journal of School Psychology* in 1963, the field had no direct journal outlet for its research and professional literature. Before then, the field relied upon an assortment of journals in psychology and education, including *American Journal of Psychology, American Psychologist, Journal of Educational Psychology, Journal of Consulting Psychology* (now *Journal of Consulting & Clinical Psychology*), *Pedagogical Seminary* (now *Journal of Genetic Psychology*), *Psychological Bulletin, Psychological Clinic*, and *Psychological Review* (Fagan, 1986a). Attending the growth of school psychologists since 1960, the growth of school psychology journals was rapid and included the publication of *Psychology in the Schools* in 1964, *School Psychology Digest* (now *School Psychology Review*) in 1972, *School Psychology International* in 1979, and *Professional School Psychology* (now *School Psychology Quarterly*) in 1986. Related journals, including those mentioned earlier, have continued to be important, including *Exceptional Children, Journal of Learning Disabilities, Journal of Psychoeducational Assessment, Professional Psychology: Research & Practice*, and *Special Services in the Schools*, as well as a growing number of journals on specific techniques or disorders.

Trends in the publication of books about school psychology appear in French (1986) and Whelan and Carlson (1986). These surveys identify the chronological order and significant content changes of books in the field. In brief, the earliest book specifically about school psychological services was published by Gertrude Hildreth in 1930; a period followed in which few books were published, including the Thayer Conference proceedings, and then a surge of books occurred beginning in the 1960s. The number and diversity of books published follow the growth pattern for journals from 1960 to the present. Despite a paucity of school psychology books and journals before the 1960s, the field has been served by many literary sources throughout the century (Fagan, Delugach, Mellon, & Schlitt, 1985).

Organizations

Organizational entities exclusively serving school psychologists originated with the Division of School Psychologists of the American Psychological Association (Division 16–APA) established in 1944–45, which evolved from the Educational Section of the American Association of Applied Psychologists (AAAP), established in 1937. Prior to the existence of these organizations, school psychologists appear to have been members of various groups, including the American Psychological Association (founded in 1892) and its offshoot the American Association of Clinical Psychologists (founded in 1917), which became the APA Section of Clinical Psychology in 1919; and the Association of Consulting Psychologists (founded in 1930), which evolved into the AAAP. Although some school psychologists were members of the National Education Association, throughout the first half-century most did not belong to any professional organization for psychologists (Fagan, 1993a). Division 16–APA was the only national-level organization for school psychologists until the founding of the National Association of School Psychologists (NASP) in 1969. For the past 25 years, both Division 16 and NASP have served as national representatives of school psychology's interests. The founding of the American Psychological Society in 1988 and the American Association of Applied and Preventive Psychology in 1990 represent increasing organizational diversity. Their effect on school psychology remains to be seen, and only a small percentage of school psychologists have become members.

The earliest state association for school psychologists appears to be that founded in Ohio in 1943. The growth of such groups was gradual, and by 1969 there were only 17 state associations, several of which were sections of their respective state psychological associations and affiliates of the APA. Growth in the number of states having separate school psychology associations that affiliated with NASP was rapid in the 1970s and 1980s (Fagan, Hensley, & Delugach, 1986). At present, every state has some form of association, and in some states more than one group exists.

Roles and Functions

Twentieth-century American education has been characterized by increased segmentation and sorting of children, presumably to intervene in their lives in more meaningful ways. The sorting function of education has a long tradition dating to the acceptance of compulsory schooling and the employment of experts, including psychologists, to assist in the segmentation of students. The sorting for interventions has ranged from school lunch programs, Title I, vocational education, advanced placement or honors classes, to nearly a dozen categories of special education. It is common for large school systems today to have numerous specialized programs operating concurrently.

As part of this growing bureaucratic process, school psychologists have served two primary functions (Fagan & Wise, 1994). The first has been a role of sorter, in which the most visible function has been the psychoeducational assessment of children for placement in special education programs. In earlier decades, this role was predominantly psychometric, although the conceptualization and practice of assessment has broadened in recent decades as a result of legislative and litigational initiatives and shifting problem-solving strategies. School psychologists now work as members of service teams in which a more comprehensive approach to assessment is taken.

A second role, that of repairer, has engaged school psychologists in individual and group interventions. In earlier decades this often involved academic remediation and counseling. More intensive interventions, such as psychotherapy, were often restricted, prohibited, or considered too time consuming or too costly to be done by district-based practitioners. This practice has changed in the past 30 years as a result of broader training, supervised internships, greater availability of school-based practitioners, and a gradual shifting of administrators' thinking in the direction of serving children's mental health as well as academic needs.

A third role, consultation, could be considered a special case of the repairer role, but it has received so much attention since the 1960s that usually it is considered a separate role. There are many instances of consulting in the early literature of our field, but the in-depth consultation characteristic of recent times was only occasionally practiced and seldom researched. All school psychologists occasionally consult with others, but that does not mean they are engaged in consultation. To function effectively in the consultant role, a practitioner now requires specialized preparation and experience.

A fourth role is that of engineer, in which the practitioner works with overall service delivery schemes. This extension of the consultation role to systems analysis and development focuses its assessment and interventions at systemic needs, not the needs of individual children, parents, or educators. Until recent times, this role was rarely performed by school psychologists.

Many school psychologists enjoy broader roles and functions than others did in earlier decades. However, most continue to practice the two traditional roles of sorter and repairer, with attendant functions of traditional psychoeducational assessment and one-to-one or group interventions with children. The similarity of roles over time gives a false impression that little has changed in the practice of school psychology. The technical quality and knowledge about assessment and intervention functions (e.g., cognitive and achievement tests, behavior modification, or behavioral consultation) have strengthened the roles of school psychologists. Perhaps the most striking changes have occurred in the context of practice. Just 25 years ago most school psychologists worked without requirements for parent/guardian permission, multidisciplinary teams, annual reviews and IEPs, and least restrictive environment placements. The category of learning disability, now the largest area of exceptionality, was just gaining official recognition. Public laws 93–380, 94–142, and 99–457 were far off in the future. Most special education services were provided in segregated programs. Among the more frequently given tests were the WISC, Stanford-Binet (1960 edition), Illinois Test of Psycholinguistic Abilities, Frostig Developmental Test of Visual Perception, and the Bender Motor Gestalt Test. The school psychologist typically held a Master's degree with a practicum and little or no internship experience. In some settings the school psychologist served in a dual capacity as psychoeducational assessment specialist and coordinator of special education. He/she was a one-person M-Team. Although some aspects of role and function have persisted, there has been considerable change in our field.

Problem-Solving Strategies

Although their approach to the task has varied over the century, school psychologists have been employed to help alleviate the problems of children and their schooling. This discussion of problem-solving approaches will focus only on the sorter and repairer roles — that is, the traditional child study approach to services. Early descriptions of practice reveal a problem-solving strategy that focused exclusively on the individual child. This strategy sought solutions to children's school problems by studying their identifiable skills and the presumed underlying abilities, traits, or personality characteristics. Problems were considered to rest with the skills and characteristics associated with the child, and the solutions rested with their alteration. Diagnosis and intervention were child-centered. Assessment methods included questionnaires, interviews of the child, parent, or teacher, tests (both standardized and unstandardized, normed and unnormed), inspection of the child's work, school and health histories, and occasional classroom observations. The rapid acceptance of the Binet and Simon intelligence scales and standardized norm-based achievement tests was attributable to the apparent objectivity they brought to an assessment process fraught with varying opinions about classification and degrees of symptomatology. The new tests added scientific respectability to problem solving by quantifying the extent of a problem and contributing to greater objectivity in classification. Interventions included brief counseling, remediation of academic skills, and an expanding array of instructional and community-based programs in special education.

In part as a result of debates over nature and nurture, as well as the increasing influence of behavioral psychology, the problem-solving strategy of school psychologists gradually expanded to include the assessment and intervention of persons and factors beyond the individual child. The most obvious shift of focus was from the child to the parents and guardians. For example, for many years it was believed that certain child problems (e.g., autism) were etiologically linked to inadequate parenting (often construed to mean inadequate mothering in an era when societal consensus held that mothers were the primary child caretakers). The focus also expanded to classroom variables, including teacher characteristics and the characteristics of their teaching. As this strategy continued to expand, the notion of problem-solving assessment broadened to the concept of ecological assessment. The child continued to be the focus of study, but only in relation to the other variables in the child's environment and especially the child's unique interaction with this environment. Logically, the etiology of children's problems expanded as well. Failure was no longer viewed in terms of child variables but in terms of other factors, separately or in combination with child variables (e.g., ineffective teaching with children having specific learning deficits).

The methodology continued to include standardized and unstandardized, normed and unnormed tests. Also included were an array of measures, formal and informal, of peer relationships and sociograms, attitude toward school, parenting, classroom climate and teaching, socioeconomic status, and formalized observations of child and peer behaviors (e.g., event and time sampling). Interventions continued to include the earlier forms, though with greater sophistication in special education programs and diversified therapeutic techniques (e.g., client-centered, rational-emotive therapies, and behavior modification) applied to groups as well as to individuals. Problem solving was still focused on the child, although increasingly school psychologists relied upon indirect interventions such as teacher and parent consultation (see Kehle, Clark, & Jenson, 1993; Sandoval, 1993).

The ecological viewpoint (including reciprocal determinism), with its contention that variables external to the child are worthy of study and intervention, has strongly influenced school psychology for the past three decades (see, e.g., Elliott & Witt, 1986). In recent years, the problem-solving task has shifted some of its focus back to the child in the form of directly measured observable skills and corresponding direct interventions. At least where the "high incidence" problems of children are concerned (e.g., learning disability, educable mental retardation, emotional and behavioral disturbance), the shift has been toward disavowing underpinning normative characteristics in favor of direct interventions in observable academic and social behaviors. A longstanding paradigm of assessing skills through underlying supportive characteristics (e.g., intelligence) has shifted to a paradigm of direct assessment of skills and direct remedial instruction irrespective of underlying abilities or traits. The current conceptualizations are identified with an "outcome education" orientation under various names, including authentic-, curriculum-, performance-, and portfolio-based assessment. These are variations on earlier themes of criterion-based assessments that have been popular at different times in our history. Other shifts in problem solving have focused on parent and teacher effectiveness, and the child's family constellation. It is now common for school psychologists to consider family variables in both their diagnostic and intervention efforts, and systems have been developed for family assessment and therapy.

In summary, school psychologists have always been identified with one or more problem-solving strategies, the nature of which has shifted over time. Although it is easy to look back with disdain on the practices of earlier eras, earlier practices were influenced as much by broad societal ideologies of the period as by professionals' lofty aspirations. For example, the recent clamor of interest in the family has occurred after an era of governmental, societal, and professional alarm over family deterioration. There was less focus on the family in the 1950s, an era often viewed nostalgically as one of family strength. The irony points to our tendency to draw attention to phenomena for study after the fact. The shifting strategies toward child study are probably less "on the cutting edge" of practice than they are on the backside of educational and psychological research, and societal acceptance of the changing spheres of child influence.

In retrospect, we observe stages of development in problem-solving approaches associated with a broadening recognition and acceptance of the spheres of influence on children. While clear-cut temporal or strategy demarcations cannot be specified, the expansion of spheres generally has been from child, to parents and teachers, to family and school, to community and society. Even though the stages overlap and continue to be observed in the varied practices of professional psychologists, comprehen-

sive assessment and intervention practices have expanded accordingly.

Critics of traditional school psychology contend that it was not based on a problem-solving model at all. However, all problem-solving models involve assessment and intervention. The traditional model identified the school psychologist primarily with assessment to determine eligibility for interventions most often provided by others via special classrooms and programs. Most traditional school psychologists were, and many still are, not effectively linked to the intervention side of problem solving. But that does not mean the overall process is outside the realm of problem solving. Employing an assembly line approach to automaking, instead of having each worker build the entire car, does not make the assembly line outside the realm of automaking. Further, the shift from processing assessment to functional assessment does not mean that the former was outside the realm of a problem-solving model. What has changed is simply the nature of the assessments advocated and the involvement of the school psychologist throughout the assessment and intervention. Some advocates of the "new" problem-solving approaches have chosen to dissociate themselves from the earlier approaches to practice, preferring reform to transition in practice. However, even the current *zeitgeist* is historically linked to earlier approaches known as diagnostic teaching during Witmer's time, and precision teaching, directive teaching, and mastery learning in the last two decades. The recent shifts in problem-solving strategy could benefit services in the long run if they successfully drew greater attention to the importance of interventions and recognized the complementary relationship between child-centered and ecological assessment approaches, and normative-based and criterion-based measurement. The shift toward collaborative inclusion of parents and teachers as peers in the problem-solving process could also have positive implications. Finally, perhaps the school psychologist will earn a more balanced role than in the past, as "repairer" instead of "sorter" of children's problems.

Best Practices in Planning School Psychology Delivery Programs

Mel Franklin
Amphitheater Public Schools, Tucson, Arizona

OVERVIEW

The increasing complexity of society has placed greater demands upon the school, the school psychologist, and school psychology delivery programs to add to their repertoire of "traditional" services (Franklin & Duley, 1991). School psychology delivery programs that are predicated on refer-and-test models of service, school psychologists as gatekeepers for special education, a search for pathology, or a commitment to reactive versus preventive services, which perpetuate a static approach to delivery, may find their future survival at best questionable. It is imperative that school psychologists make choices in their professional services that match the needs of the children and youth that we serve and "enhance the likelihood of effective intervention" (Reschly & Grimes, 1990, p. 425). Oakland (1986) suggests that school psychologists must work to ensure that their services are cost-effective, have community support, and are demonstrated to be beneficial compared with what occurs without school psychology services.

The purpose of this chapter is to provide direction for school psychologist practitioners or individuals responsible for establishing or redesigning school delivery programs for psychology services. This chapter will include (a) a review of programs that work, (b) organizational considerations, (c) program administration and supervision, (d) comprehensive service delivery, and (e) considerations for the future.

BASIC CONSIDERATIONS

The National Association of School Psychologists (NASP) *Standards for the Provision of School Psychological Services* (NASP, 1992b) provides the position of the Association "regarding the delivery of appropriate and comprehensive school psychological services." It is suggested that individuals who are establishing or modifying existing school psychological services possess a thorough working knowledge of these NASP standards.

To successfully establish or modify a program of school psychology service delivery, the school psychologist may benefit from sensitization to programs that work. Although there exist numerous exceptional school psychology programs, few have recently been described in the literature. A review of six award-winning innovative school psychology delivery programs is provided.

Beginning in 1982, Division 16 (School Psychology) of the American Psychological Association (APA) and the National Association of School Psychologists (NASP) initiated an award to recognize exemplary school psychology service units (Telzrow, 1989). "The award represents a positive public citation for excellence in providing comprehensive psychological services in the school" (Telzrow, 1989, p. 59) and recognizes a psychology services unit that is "exemplary in the range and quality of services offered in the schools" ("Division Spotlight," 1988). Recipients of the APA Division 16–NASP Award for Excellence have included (1) Memphis (Tennessee) City Schools Mental Health Center (1982); (2) Gwinnett County Schools Psychological Services (Lawrence, Georgia) (1985); (3) Amphitheater Unified School District School Psychology Department (Tucson, Arizona) (1987); (4) Broward County Schools Psychological Services (Florida) (1990); (5) Cherry Creek School District Mental Health Team (Englewood, Colorado) (1990); and (6) Cypress–Fairbanks Independent School District Psychological Services (Houston, Texas) (1990) (Telzrow, 1989; L. W. Roosa, personal communication, May 24, 1993).

Memphis City Schools Mental Health Center

The Memphis City Schools Mental Health Center (MCSMHC) is a service unit to the Memphis City Schools as well as an incorporated not-for-profit mental health center (Paavola, Hannah, & Nichol, 1989). The unit is led by the director, who is a licensed psychologist with competencies in school psychology. The director reports to the same assistant superintendent as do the heads of special education, guidance, and research (Paavola et al., 1989). The MCSMHC is committed to prevention and prereferral intervention through the use of school support teams (S-Teams); this has yielded a 25% drop in initial special education referrals. The MCSMHC requires each staff member to obtain a minimum of 50 staff development hours each year. The MCSMHC provides mental health services that include parent/teacher consultation; prevention activities; individual, family, and group counseling; and psychological assessment (Nichol, 1993). The MCSMHC is also involved in the provision of alcohol and drug prevention and intervention activities, violence reduction efforts, an adolescent parenting program, and treatment services for abused and neglected students. Paavola et al. (1989) recognize that many issues will come to prominence in future years that will impact on the well-being of children and youth. Although it may be difficult to anticipate appropriate responses to each of these issues, the MCSMHC appears to be addressing these issues as they arise by maintaining its focus on providing a comprehensive array of services.

Gwinnett County School Psychological Services

Bush et al. (1989) reported that Gwinnett County (Lawrence, Georgia) has experienced tremendous growth in their student population without a concomitant increase in psychological services staff. Historically the Gwinnett County School Psychological Services program has been responsible for assessment of students for possible eligibility for special education programs. This diagnostic model of service delivery was found to be inadequate owing to the increasingly diversified population. Following a needs assessment, the program formulated a more comprehensive model of services that combined traditional assessment functions with consultation activities. The mission of the program was to provide comprehensive psychological service. The program utilizes a school-based model of consultation proposed by Gutkin and Curtis (1982) with emphasis on collaborative problem solving and the use of student study teams. The Gwinnett County program is directed by a licensed/certified professional psychologist and uses a process of peer review. Bush et al. (1989) report that the program has established a goal to include research and publication. Bush et al. (1989) also state that by more effectively managing the assessment aspects by the department and focusing on prevention, the perceived role of the psychologist has changed from gatekeeper of special education to that of child advocate with expertise in many areas.

Amphitheater School District School Psychology Department

In the Amphitheater School District in Tucson, Arizona, the School Psychology Department head is a certified professional school psychologist who holds a supervisory school psychologist certificate and is licensed by the State Board of Psychologist Examiners. The department head provides school psychology services to two district schools and reports directly to an associate superintendent. The program adheres to a model of behavioral consultation based upon the work of Bergan (1977). If initial consultation is not successful or more formal intervention appears warranted, a student study team (SST) model is employed to generate alternative intervention strategies. The primary function of the school psychologist is advocacy for the student to attempt resolution of the referral problem in the least restrictive setting (Franklin & Duley, 1991). Use of the SST has allowed the development of an additional creative and dynamic problem-solving process with a multidisciplinary team approach. Each school psychologist is expected to participate in research activities as well as the dissemination of applied research. The Amphitheater School Psychology Department, through the use of a consultative model, has utilized a growing research base across a number of fields of psychology to address concerns of students in an educational setting. The use of this model has led to a decrease in per capita referrals during a period of increasing student population. The staff has been better able to provide increased levels of behavioral consultation, direct service, in-service, and related efforts.

Broward County Schools Psychological Services

The Broward County School District is the nation's eighth largest school system, serving a diverse population of over 180,000 students and employing approximately 75 school psychologists (L. W. Roosa, personal communication, June 11, 1993). Psychological Services is a department within Student Services, which is a component of the Division of Instruction and Program Services. The Psychological Services Unit is headed by a director who is an experienced school psychologist. The director administers the program and is responsible for the programmatic aspects of the services. The direct supervision of school psychologist is provided by Area Coordinators of Student Services who are experienced school psychologists. The Psychological Services Department provides a comprehensive range of services that focus upon prevention and consultation activities. School psychologists participate on school-based child study or intervention assistance teams. Collaborative problem-solving consultation activities are available to teachers, principals, and parents. The special features of the department also include a minority/bilingual traineeship program, involvement in a program for young socially maladjusted students, the use of a computer data base to monitor assessment cases, biweekly professional development activities, and a departmental newsletter, distributed to each school, members of the school board, district administrators, and state school psychology trainers, that is designed to articulate the role and the accomplishments of the staff members. As a function of the size of the department and the staff selection procedures, the diverse staff has school psychologists with expertise in low-incidence handicaps (e.g., autistic and motor-sensory-impaired) and bilingual evaluations. Bilingual school psychologists have participated in the development of informal academic assessment instruments in both Creole and Spanish.

Cherry Creek School District Mental Health Team

The Cherry Creek Schools Mental Health Team (CCMHT) consists of approximately 50 psychologists and social workers who serve a population of 28,000 students in a suburban area near Denver, Colorado (W. M. Porter, personal communication, November 4, 1993). The CCMHT pairs a psychologist and a social worker in a building as a mental health team. The mental health team determines the needs of an individual school and tailors services to these identified needs. The services may include consultation with teachers, parents, and administrators; curriculum-based assessments and environmental and biological assessments; direct services to students through individual and group counseling and crisis intervention; and counseling and support for the mental health needs of teachers and staff with a connection to an employee assistance program. The CCMHT utilizes a comprehensive community approach in an attempt to develop strategies to meet the needs of the individuals and systems it services. The CCMHT is directed by a coordinator who reports directly to the director of Pupil Services. The CCMHT demonstrates a commitment to the training and supervision of future school psychologist practitioners. The CCMHT offers weekly seminars for school psychology interns and practicum students completing placements in the district. The CCMHT also demonstrates a strong commitment to the professional growth of its mental health team members. Psychologists are encouraged to pursue cultural and international exchanges with psychologists from other settings and to conduct research projects that foster individual and professional growth.

Cypress-Fairbanks I.S.D. Psychological Services

The Cypress-Fairbanks Independent School District Psychological Services in Houston, Texas is overseen by a director of psychological services, who is a licensed psychologist and a certificated school psychologist and the director reports directly to the associate superintendent in charge of administration (K. A. Young & K. S. Grier, personal communication, May 28, 1993). The district has grown from a population of 7,000 in 1968 to approximately 46,000 in 1993. The unit employs five doctoral interns annually and is approved as an APA Professional Psychology internship site. The program uses a combination of psychologists and educational diagnosticians. In psychoeducational assessments the psychologists are responsible for the emotional and personality components of the assessment, while the diagnosticians evaluate the intellectual, academic, and adaptive behavior components. The department involvement throughout the district has significantly expanded in response to the behavioral and emotional needs of the district's ever-growing population. The Department of Psychological Services mandate is to "provide quality, broadly based psychological services to the entire school district through a comprehensive psychological service delivery system." The department has targeted primary prevention, indirect service through consultation, the provision of direct services, and coordinating and complementing the community mental health and education system as vehicles to meet the mandate (K. A. Young & K. S. Grier, personal communication, May 28, 1993). The staff demonstrates a commitment to continuing professional development by participating in weekly training colloquiums and program development meetings.

A seventh program, described in the literature, is presented for your information.

Minneapolis Psychological Services

Canter (1991) outlines a comprehensive data-based model of school psychological service delivery for all 44,000 children and youths within the Minneapolis public schools. Centralized administrative supervision for psychological services is provided by a chief psychologist. However, since the 22 full-time-equivalent school psychologists in the Minneapolis School District have traditionally been assigned to specific schools as building staff, they are responsible directly to principals (Canter, 1991). Canter (1991) reports that a delivery model that was largely assessment-driven was replaced with a new model for service delivery that emerged from a change in focus to indirect services, which was stimulated by the changing character of the student population, the loss of revenue from declining enrollment, and the interests and allocation of staff. School psychology services became an "increasingly consultation-based system providing services to the teacher and administrator at least as often as those directly provided to the student" (Canter, 1991, p. 53). The department provides a proactive system of accountability that enlists a systematic process of documenting and evaluating the delivery model. Procedures have been developed to enable school psychologists "to monitor their roles in service delivery, examine referral issues, document staff development needs, and measure the effectiveness of interventions, as well as track changes in these areas over time" (Canter, 1991, p. 56). The district uses a curriculum-based measurement (CBM) model for measuring the students' progress and for determination of eligibility for special education. A focus upon indirect service delivery has allowed school psychologists to be actively involved in curriculum planning, research, staff training, development of educational programs and policy, and maintaining professional visibility (Canter, 1991). The delivery model is not seen as static, but as a "continuing evolution of theory and practice" that is constantly being "modified in response to internal and external needs and changes" (Canter, 1991, p. 73).

The aforementioned innovative school psychology delivery systems appear to possess in aggregate the following characteristics:

1. Highly qualified generalist/specialist practitioners and a wide range of expertise within each department.
2. The delivery of expanded and comprehensive school psychology services to meet the needs of *all* students.
3. A commitment to prereferral intervention/prevention activities.
4. The use of school-based collaborative consultation.
5. Linking assessment to instructional intervention rather than to classification alone.
6. Articulating departmental successes.
7. Accountability through efficacy data.
8. Malleability.
9. A focus on continuing professional development.
10. Departmental autonomy and clinical supervision and evaluation by a school psychologist.
11. Involvement in research.
12. A commitment to the training of future school psychologist practitioners.

BEST PRACTICES

There is no unitary ideal delivery system of school psychology services. A best practices model for an individual practitioner requires careful consideration of numerous variables. This section reviews organizational considerations, program administration and supervision, and ten basic components of comprehensive service delivery for a successful school psychology program.

Organizational Considerations

Placement of the school psychology delivery program within a school district's organization pattern (Talley, 1990) is seen as a critical issue for consideration. Talley (1990) provides a review of four basic *within-district* models of service delivery to school psychology: (a) as a separate program, (b) within special education services, (c) within special education, and (d) building-based. School psychology as a separate department allows for greater professional autonomy and visibility as a means to facilitate the delivery of comprehensive school psychology services. This model allows for practice that is less encumbered by traditional association with special education. The director can provide both administrative and clinical supervision and often reports to an assistant or associate superintendent. In a second model of school psychology service delivery, staff reports to a director of student services, who may not be a school psychologist. Some independence from special education may be available in this model; however, there often exists a lack of appropriate school psychology leadership and administration, as well as appropriate clinical supervision of practice. In a third model, presented by Talley (1990) and commonly encountered, the school psychology program is subsumed within the special education department. In some districts school psychologists are chosen to direct the school psychology program, but often nonpsychologists are asked to assume this supervisory role. Among the problems that might arise from the choice of a nonpsychologist director is a lack of knowledge of practice guidelines, professional standards and ethics, and the comprehensive nature of school psychology services that can be provided. Staunch advocacy for expanded school psychology services may also be absent. The fourth model, building-based psychology, provides for a school psychologist assigned to one school or based in one school with the provision of services to several schools. Supervision and evaluation of practice is provided by the building principal. In this model, school psychologists generally lack appropriate clinical supervision and may experience a sense of isolation from fellow district school psychologists. Talley (1990) outlines a fifth model of regional service delivery (often found in rural school districts) in which the school psychologists are employed by a regional service center or cooperative.

Program Administration and Supervision

The provision of appropriate supervision of school psychologists is *required* by professional associations (APA, 1981; NASP, 1992b), is *desired* by practitioners (Zins, Murphy, & Wess, 1989), and is an *integral component* to the success of a school psychology delivery program. NASP has proposed that supervision be made available to all practicing school psychologists "to an extent sufficient to ensure the provision of effective and accountable services" (NASP, 1992b, p. 39). NASP suggests that a ratio of one supervisor for every ten school psychologists be maintained with an equivalent ratio for part-time supervisors, and that school psychologists receive one hour per week of face-to-face supervision during the first 3 years of full-time employment (NASP, 1992b). Following the first 3 years all school psychologists are to continue under supervision and/or peer review (NASP, 1992b). A supervising school psychologist is defined by NASP as a professional psychologist who has completed three years of supervised experience as a school psychologist and has met credentialing requirements (NASP, 1992b). Coursework or other training in the supervision of school personnel is seen as desirable (NASP, 1992b) and as needed (Ross & Goh, 1993).

APA suggests that supervision should be provided by a doctoral school psychologist at a ratio of one supervisor per 15 full-time school psychology personnel, that all nondoctoral school psychologists should be supervised, and that all school psychology services staff should receive face-to-face supervision (APA, 1981; Talley, 1990). Although one might assume that these supervisory standards are commonly followed by most employers, such a commitment to supervision may be the exception rather than the rule. Zins et al. (1989) have reported that less than one in four school psychologists actually received clinical supervision. How often have practitioners observed supervisors with little or no formal training or practical school psychology experience providing clinical supervision for school psychologist practitioners? Zins et al. (1989) reported that clinical supervision was often provided by individuals whose terminal degree was not in school psychology and that less than 50% of supervision met NASP or APA professional practice standards.

The supervisor should be responsible for providing evaluation of the school psychologist practitioner with data pertaining to their personal effectiveness, as well as data pertaining to the effectiveness of the department as a whole. This evaluation should be both formative and summative. Such evaluation can assist the school psychologist practitioner in determining his or her current development level and professional strengths and weaknesses (Knoff, 1986). It is also suggested that the supervisor assess the effectiveness of the service delivery by the department and determine the match with the needs of the local constituency.

The nature, magnitude, and frequency of problematic situations in the schools seems to be changing at a rapid pace in most communities. Therefore, it continues to be the school psychologist practitioner's responsibility to assess these problematic situations and provide timely and appropriate intervention. The nature and breadth of these problems make it at times difficult, if not impossible, to possess every technical and practical skill to deal with every facet of practice demanded in the field (Knoff, 1986). It becomes the responsibility of the supervisor to match the practitioner's relative strengths with the identified needs of the constituency. It is important for the supervisor of school psychologists to provide liaison activities with other professionals in related fields. The federal and state rules, regulations, and standards to which school psychologists must adhere may be different from the rules that are applied to practitioners in related areas. It may therefore be necessary for the supervisor to define these differences to appropriate agencies or private practitioners to facilitate the continued delivery of quality school psychological services.

Supervisors of school psychologists can be most effective when they also function as school psychologist practitioners. Ideally they should "walk in the shoes" of fellow practitioners. They should always be seen as striving for individual and departmental excellence while keeping one foot in the camp of the school psychologist practitioner. Without such a frame of reference, one's supervisory effectiveness can be greatly diminished (Franklin, 1989). Any best practices model for school psychology services delivery requires adherence to the provision of appropriate school psychology practitioner supervision.

In the establishment of modification of a delivery program it is necessary that we recruit qualified practitioners. Although most school psychologist practitioners have received training as generalists (Fagan, 1990b), there may be a need to recruit individuals within specialty training to include early childhood, neuropsychology, and curriculum-based assessment. Prior to hiring a new school psychologist practitioner it may be useful for the department to assess its present needs and establish a rubric for the replacement psychologist. The supply-and-demand gap for school psychologist practitioners appears to continue to be problematic (Connolly & Reschly, 1990). Ongoing networking with state professional organizations and graduate training programs, maintenance of competitive salary schedules, and work environments that allow for school psychologists to use their diverse skills can improve both the quantity and quality of applicant pools of school psychologists. As individuals in training programs seek higher levels of required training and employment in more diverse practice settings (Fagan, 1990a), as well as a "graying" of the profession, shortages of school psychologist practitioners likely will continue in the future.

The school psychology department should foster the establishment of short-term and long-range departmental direction through the use of strategic planning to include a needs assessment, a mission statement, and specific departmental goals and objectives with measurable criteria (Franklin & Wasserman, 1992). This process allows the department to know where it needs to go, how it plans to get there, and when it has arrived.

NASP (1992b) provides guidelines suggesting a ratio of at least one full-time school psychologist for each 1,000 children and youths served. NASP recognizes that the ratio vary with the needs of the children served, the type of program served, the resources that are available, the distance between schools, and other unique characteristics (NASP, 1992b). School psychology programs should advocate at the state and local levels for a practitioner-to-student ratio that allows for the provision of comprehensive school psychological services.

In light of higher caseloads, the lack of sufficient funding in public education to provide appropriate compensation or appropriate salary increases, and increasing expectations from school psychologist practitioners (Fagan, 1990a), it can be anticipated that retaining qualified practitioners will continue to be a demanding issue. In addition issues surrounding burnout of school psychologist practitioners should also be given consideration (Huebner, 1992).

Comprehensive Service Delivery

All school psychological practice should be in full accordance with NASP *Principles for Professional Ethics* (NASP, 1992a) and *Standards for the Provision of School Psychological Services* (NASP, 1992b). The purpose of the *Standards* is to help "ensure the delivery of comprehensive services by school psychologists" (NASP, 1992b, p. 43). The following components are seen as essential to a comprehensive program.

Consultation. Central to most successful school psychology delivery programs is the use of problem-solving behavioral consultation with parents, teachers, and students themselves. "The school psychologist usually does not personally provide the intervention," but rather guidance for those that do (NASP, 1992b). Behavioral consultation generally incorporates a four-stage process in which problem identification, problem analysis, plan implementation, and plan evaluation are carried out to address students' difficulties. A basic concept of the consultation model is the collaborative interaction between the psychologist and the consultee in which the latter (most frequently a teacher) acquires novel skills to address students' needs (Franklin & Duley, 1991). It is then hoped that these efforts will provide generalization of those skills across other cases in the educational setting. In this way psychologists can use their skills more effectively in their service as mental health practitioners and team leaders in comparison with more reactive, psychometrics-based practice (Franklin & Duley, 1991). Batsche (1991) reports that consultation/intervention services can reduce special education placements by as much as 50% without adversely affecting the progress of individual students.

Assessment. Another significant component of school psychology service delivery may be psychological and psychoeducational assessment. School psychologist practitioners must employ multifaceted psychological and psychoeducational assessments of children and youths according to current best practices (NASP, 1992b). School psychologists should utilize a variety of observational, behavioral evaluation, and interview techniques, as well as the traditional use of both normative and criterion-referenced instrumentation. All assessment should be linked to instructional intervention. Reschly (1988) cautions that assessment for classification will be replaced by assessment for the express purpose of developing interventions to be implemented in the classroom. Direct assessment techniques such as curriculum-based assessment (CBA) are seen as important competencies for school psychologists (Reschly, 1988).

Direct services. Direct service to students is traditionally seen as "techniques supplied in a face-to-face situation, which are designed to enhance the mental health, behavior, personality, social competency, academic, or educational status of the student" (NASP, 1992b, p. 45). Both individual and group counseling activities would fall under this heading. It seems that school psychologists are consistently dealing with crisis intervention situations that result in the "interrupted day." Often they are the front-line mental health professionals in the schools and are therefore called upon to provide intervention services on an as-needed basis. Thus, the best devised schedule for a school psychologist practitioner can go out the window on any given day, although the demands of the existing case load and mandated timelines continue in force.

Prevention. Primary and secondary prevention rather than tertiary prevention (treatment) should also be seen at the heart of a successful school psychology delivery program. Primary prevention seeks to change the incidence of new referrals by intervening proactively before a disorder occurs (Hightower, Johnson, & Haffey, 1990). For example, prosocial competencies can be increased through education and environments can be modified to reduce or counteract harmful circumstances. Primary prevention efforts call for proactive efforts to prevent problems from occurring, rather than attempts to reduce existing problems (Hightower et al., 1990). Secondary prevention is generally seen as identification of problems during the earliest stages and intervention before the problems become severe. This paradigm shift from treatment to prevention (Hightower et al., 1990) is seen as a critical strategy for practicing school psychologists who desire to provide a successful school psychology delivery program. The present need for more school psychology services and the continuing shortage of school psychologist practitioners suggest the need for further adoption of effective prevention programs (Hightower et al., 1990). School psychologists must continue to place their energy on the "front end" of the prevention–treatment continuum rather than on the "back end" of reactive crisis intervention.

Research. NASP suggests that school psychologists "design, conduct, report, and use the results of research of a psychological and educational nature" (NASP, 1992b, p. 45). Keith (1990) defines such research as "activities designed to produce new scientific knowledge or to use the knowledge to improve school psychological practices" (p. 207). Keith (1990) sees the need for school psychologist practitioners to be competent consumers of research and to act as distributors of research, and for some school psychologists to conduct research. For practitioners involved in conducting research, the use of quasi-experimental research, single-case designs, reversal designs, and multiple baseline designs holds promise (Keith, 1988). School psychologist practitioners should be involved in one or more levels of research to bring about a quality school psychology delivery program. Stoner and Green (1992) suggest that 100% of a school psychologist practitioner's time should be involved in doing research, in that practice and research should become one and the same.

Kratochwill, Schnaps, and Bissell (1985) describe four general types of research in school psychology: historical research, descriptive research, passive observational methods, and experimental research. They also provide some explanation and possible solutions for school psychological practitioners who have not been actively involved in research or the use of research findings. Franklin and Sabers (1987) have suggested that active participation in research is almost certain to be accompanied by additional learning and professional development. Reading and discussing the literature during the planning stages of a study are likely to produce a better-informed practitioner. The credibility one gains for oneself, the service unit, and the district should not be minimized. In this day of static or decreasing budgets for school psychology, it becomes more important for the practicing school psychologist to maintain high visibility and become more indispensable. The school psychologist as researcher can become more clearly indispensable, both as disseminator of research findings and as one who can provide answers to questions needing investigation.

Anything that is worth doing in the school setting warrants consideration for sharing with fellow professionals (Franklin & Sabers, 1987). This sharing may take the form of oral presentations to district staff, papers presented to local, state, or publications in national professional groups, papers in state and regional publications, book chapters, or publications in national refereed journals. "If it is worth doing, it is worth telling your fellow psychologists about it."

During routine assessment, Franklin (1983) observed consistently lower subtest scores obtained on a subtest of a commonly utilized individually administered reading achievement test. This concern led to a decision to study this subtest within the psychoeducational role of the practicing school psychologist. Questions surrounding design, random assignment, and statistical analysis were quickly resolved through consultation with colleagues at a local university. This effort led to a publishable article based on data that were gathered as part of routine reevaluations of a relatively small number of students. The reading subtest was subsequently modified by the instrument's author. This revision led Franklin, Fullilove, and Sabers (1985) to further assess the author's modifications. Again, this research was accomplished as part of a routine pre–post testing battery for development of individual education plans and made use of a school psychology practicum student. NASP's initial efforts to match school psychologist practitioners' research questions with graduate students seeking research topics appear to hold great promise of increasing the body of research data in the profession.

Liaison and coordination. NASP advocates that school psychologists establish and maintain relationships with other professionals who provide services to children and families and "collaborate with these professionals in prevention, assessment, and intervention efforts as necessary" (NASP, 1992b, p. 43). School psychologist practitioners can assist in coordinating the services of mental health providers from other agencies to provide a continuum of service for students (NASP, 1992b). It is likely that these liaison and coordinating roles for psychologist practitioners will become increasingly important.

Supervision, training, and mentorship. School psychology departments have a responsibility to provide training and development of new school psychologists. In the provision of training sites for introductory school psychology students, practicum students, and internship students, such an emphasis allows for continued sharing of existing expertise with a school psychology practitioner as well as the learning provided to the practitioner by students in training. It is also important for school psychology departments to work with university trainers in the area of supervision of students participating in school psychology practicums and internships. These activities help ensure the existence of a future pool of quality school psychologist practitioners (Franklin, 1989). New school psychologist practitioners should be assigned to school psychologist mentors to assist in shepherding them into the politics and nuances of the school district.

Continuing professional development. There is a constant shift in the needs of our constituency. These needs may in part be met through the provision of continuing education and professional training to the school psychologist practitioner. This can be accomplished through the dissemination of information between professionals within a school's psychological services department, through contracting with experts for in-service training, and through the participation of practitioners in conferences and workshops that teach new, or hone existing skills (Franklin, 1989). McKee, Witt, Elliott, Pardue, and Judycki (1987) suggest that talking to colleagues, exploring local needs, and requesting and sharing specific information may be as useful in obtaining information as employing outside consultants, having school psychologists attend workshops, and using professional development materials. It may be necessary for the supervisor of school psychology services to inform or educate central office and building administrators, as well as members of the governing board, of the importance of continuing professional education and professional training activities for school psychologist practitioners.

"The practice of school psychology will continue to change significantly over the course of the next years as new knowledge and technological advances are introduced" (NASP, 1992b, p. 46). It will therefore be necessary for the school psychologist practitioner to remain knowledgeable about these changes in practice. It is suggested that school psychology service programs that require or encourage school psychologist practitioners to acquire and maintain credentialing by the National School Psychology Certification System (NASP, 1988) assist in the continued training and honing of the existing skills of its practitioners. Continued training and the reinforcement of existing skills are critical to the maintenance of quality school psychology delivery programs (Franklin, 1989).

Accountability. Accountability of the service delivery program is an important component as well (NASP, 1992b). Zins (1984) defines accountability as an

> evaluative effort designed to gather systematically information relevant to the performance assessment of school psychologists. It enables them to demonstrate the effectiveness of their services to others, and it provides an evaluation of how well they have met their performance objectives. It is concerned with both quantitative and qualitative aspects of practice and addresses both individuals and groups. It is particularly useful in improving service delivery and enhancing professional development. (p. 58)

Batsche (1991) suggests that school psychological practitioners collect data regarding efficacy in relation to costs and consumer satisfaction, as well as the effectiveness of service delivery. "If you are a supervisor or a school psychologist in a district hard hit by financial difficulties, ask yourself whether or not you are providing information that convinces superintendents and boards of education of the worth of school psychological services" (Batsche, 1991, p. 2). In the Minneapolis Psychological Services Program previously described, accountability data brought about modifications in school psychology practice as a function of the outcome of the accountability system (Canter, 1991). As individual school psychological practitioners and as a profession we cannot ignore the need to regularly evaluate our services (Zins, 1990). Providing accountability data must become a routine component of school psychology services.

High visibility. It is also important to report the accomplishments of the school psychology department to the teachers, administrators, governing board members, and constituents of the district (Franklin, 1989). Maintaining high visibility for a successful school psychology delivery program can generate future support for the acquisition of additional staff positions, the provision of continuing education and professional training, and the delivery of nontraditional practice opportunities for the school psychologist (Franklin, 1989). Attention to public image must be seen as a major factor in the role of the school psychologist and the services that are provided (Kelly, 1990). The advice, attributed to the late Congressman Adam Clayton Powell, that "you will never hear any music, if you don't blow your own horn" (K. P. Dwyer, personal communication, March 8, 1994) should be seriously considered by school psychologist practitioners.

Future Considerations

Hutton, Dubes, and Muir (1992) report that school psychologists spend 40%–60% of their time in assessment activities. Will (1988) suggests that the traditional role of school psychologists as gatekeepers for the entry to special education and reentry to regular education needs to shift from reactive to proactive, in which learning and instructional problems are prevented. "This shift will require greater emphasis on instructional variables that include the curriculum, task features, teaching functions, and instructionally based assessment procedures" (Will, 1988, p. 478).

Reschly (1988) believes that the "character of school psychology at the dawn of the 21st century will be markedly influenced by how we manage the challenge of special education reform and the necessary revolution" (p. 472). Kavaleski (1988) is of the opinion that

> school psychologists have a unique opportunity to alter contingencies that influence their own practice. Accepting this challenge can lead to the establishment of school psychology in a reformed system. Ignoring the opportunity will lead at best to business as usual and at most the demise of a discipline. (p. 483)

Continued professional development will be a component necessary to the future delivery of school psychological services. As practitioners "shift in focus from a search for pathology to educational attainment" (Myers, 1988, p. 167), it will be advantageous to acquire and hone skills in curriculum-based assessment for both formative and summative purposes.

As school psychology service delivery programs continue to experience static or declining budgets, five issues will demand scrutiny.

1. Overcoming resistance by school psychologists, teachers, and administrators as practitioner roles change from refer-and-test to prereferral intervention and prevention.

2. The need to preserve school-based school psychologist positions (NASP, 1993).

3. The provision of efficacy data for school psychology services (Batsche, 1991).

4. Attracting and retaining qualified school psychologist practitioners.

5. The hiring of individuals with less comprehensive training as educational diagnosticians or psychometrists.

SUMMARY

As school psychology delivery programs are asked to constantly reexamine their roles, functions, and skills, they must resist the temptation to remain locked into models of delivery that are "comfortable." There is no single best way to deliver effective school psychological services. However, the NASP *Standards for the Provision of School Psychological Services* (NASP, 1992b) provides exceptional direction for individuals who are planning or modifying existing school psychology delivery programs. The chapter reviewed organizational considerations, program administration and supervision, and components of comprehensive service delivery for a successful school psychology program. A review of seven innovative school psychology programs reveal that they appear to possess in aggregate a series of characteristics: (a) highly qualified practitioners and a wide range of expertise within each department, (b) delivery of comprehensive services to all students, (c) commitment to prereferral intervention/prevention activities, (d) use of school-based collaborative consultation, (e) linking of assessment to intervention, (f) articulation of departmental successes, (g) accountability through efficacy data, (h) malleability, (i) continuing professional development, (j) departmental autonomy and supervision by a school psychologist, (k) involvement in research, and (l) commitment to training future school psychologist practitioners.

It is hoped that school psychology services delivery programs that are fixated on traditional roles and functions for school psychologist practitioners will strive to move from what is "real" to what may be seen as more "ideal" (Stewart, 1986).

ACKNOWLEDGMENTS

I would like to express my sincere appreciation to Darrell L. Sabers for his comments and suggestions on the initial drafts of this chapter.

Washington, DC: National Association of School Psychologists. This chapter provides distinctions between administrative and clinical supervision, organizational models for the delivery of school psychology services, and guidelines for school psychology leaders who are charged with translating theory into real-world school psychology services.

7

Best Practices in Continuing Professional Development for School Psychologists

Evelyn Fowler
Patti L. Harrison
University of Alabama

Continuing professional development (CPD) is a dynamic process that flows from the intrinsic motivation, interest, learning history, and professional context of the individual. In regard to school psychologists, it is the process by which they "actively participate and engage in activities designed to continue, enhance, and upgrade their professional training and skills and to help ensure quality service provision" (National Association of School Psychologists, 1992a, p. 46). The purpose of this chapter is to present suggested guidelines for individualizing CPD for school psychologists

OVERVIEW

In order to put CPD in an appropriate perspective so that it may be more fully appreciated, a brief history and rationale will be presented. Following that will be a discussion of CPD requirements for school psychologists, including state certification/licensure, school accreditation, and qualifications as a nationally certified school psychologist (NCSP).

Historical Background and Rationale

CPD was a rather loosely held concept prior to World War II, when it received its first official recognition under the Engineering, Science, Management War Training Act (Tucker & Huerta, 1984). Following World War II, as professionalism grew and expanded, CPD emerged as the means for assuring competence. CPD remained largely unorganized and received little emphasis until the accountability movement of the 1960s. Consumer dissatisfaction with professional inadequacies and criticism from within professional ranks themselves contributed to its revitalization. A recognition of the need for CPD by professionals grew out of introspection about competition, failure, uncertainty about how to solve a problem, and accountability demands by the public. Professionals viewed CPD as a panacea for diffusing rising public criticism, malpractice suits, loss of certification, and compulsory recredentialing. The creation of the continuing education unit (CEU) in 1970 by a national task force of the National Advisory Commission on Health Manpower and its subsequent adoption in 1971 by the Southern Association of Colleges and Schools added impetus to the CPD movement (National League for Nursing, 1974; Tucker & Huerta, 1984).

In addition to accountability and quality control, another important reason that contributed to the growth of CPD is the modern notion of professionalism as a dynamic process entailing lifelong learning. According to Houle (1980), "Every occupation . . . seeks constantly to improve itself. . . . Therefore, a lifetime of learning is required . . ." (p. 10). Houle's statement suggests that professionalism is not a static entity that is achieved on completion of a formal educational program. Rather, it should be an ongoing process, maintained by motivation for learning throughout one's professional lifetime. Professionalism should be an evolving process, expanding and taking new and more complex forms as the professional oscillates between theory and practice with each reinforcing the other (Houle, 1980).

The need to maintain skills and keep abreast of new ideas and technology have contributed to the growth of CPD as well. In recent years, the knowledge bases of professional fields have rapidly and extensively developed and expanded (Houle, 1980; Rosenfield, 1985). Numerous advances have been made in technology, medicine, pharmacology, and research methodology, to name only a few. In a rapidly developing society such as ours, skills quickly erode and become dated. The term *half-life* has been used to describe the continuous obsolescence of professional competence. The half-life concept raises the notion that professionals quickly become only half as competent to meet professional demands as they were upon graduation. In particular, the half-life of a school psychologist's training has been estimated as ranging from 3 years to 5 years (Rosenfield, 1985; Hynd, Pielstick, & Schakel, 1981).

Research has also contributed to the growth of CPD by documenting its many benefits. Some of the more salient social and professional advantages to be derived from CPD participation are self-satisfaction, documented changed behavior that has translated into improved service provision, enhancement of knowledge, improved attitude, improved skills and techniques, greater confidence, increased awareness and abilities in dealing with others, better job performance, increased salary/fringe benefits, promotion on the job, and better reputation for the employing agency (Cervero & Rottet, 1984; Houle, 1980).

Continuing education is now a recognized necessity across professions and is embraced as the means for assuring quality control, competence, and accountability among professionals (Houle, 1980; Tucker & Huerta, 1984). CPD requirements are in place nationwide for relicensure or professional standing of doctors, lawyers, nurses, school psychologists, counselors, and others (e.g., American Nurses Association [AMA], 1984, 1992; National Association of School Psychologists [NASP], 1992a, 1992b; Goldberg, 1990; Wilcoxon & Hawk, 1990).

CPD Requirements for School Psychologists

Ethical standards for school psychologists, as well as requirements for certification and renewal of licensure, emphasize the need for CPD. In its ethical standards and specialty guidelines, the National Association of School Psychologists emphasizes the obligations a school psychologist assumes for CPD and ethical behavior when initially engaging in the practice of school psychology. NASP (1992b) ethical standards state:

> School psychologists engage in continuing professional development. They remain current regarding developments in research, training, and professional practices that benefit children, families, and school. (p. 6)

NASP ethical standards specifically state that participation in CPD activities is part of the continuing obligation of a school psychologist.

The *American Psychologist*'s (1992) "Ethical Principles of Psychologists and Code of Conduct" also emphasizes psychologists' obligations for ongoing education:

> They maintain knowledge of relevant scientific and professional information related to the services they render, and they recognize the need for ongoing education. (p. 1599)

Many school psychologists employed in school districts are required to document CPD activities for renewal of their individual state certificates or continued employment in their system. Among other requirements, school system accreditation often hinges on individually documented CPD activities for all school professionals within the system. For example, in 1971 the Southern Association of Colleges and Schools implemented the CEU requirement for school professionals in order for schools to receive regional accreditation (Tucker & Huerta, 1984). Many states have CPD requirements for renewal of psychology licensure; currently, 27 states require CPD for psychology licensure renewal, compared with five or six states in 1981 ("Growth of CE Program," 1992).

Nationally certified school psychologists (NCSPs) must complete CPD requirements for national certification renewal. The CPD requirements include the completion of 75 CPD credits or contact hours (actual clock hours) in at least three of the following six skill areas: consultation, psychological and psychoeducational assessment, intervention, supervision, research, and program planning and evaluation. CPD requirements for renewal of national certification are described in NASP's CPD program, located in Appendix V of this volume.

BASIC CONSIDERATIONS

Consideration of the CPD needs of school psychologists must address three important issues. First, the educational level of school psychologists vary. Next, school psychologists perform wide and varied job functions. Finally, school psychologists serve the entire range of environments — from rural to urban to large metropolitan areas. Consequently, their knowledge base, training, skill level, and professional role are multidimensional (NASP, 1992a). Only an individualized approach to CPD can address such multifaceted needs. This section describes an individualized CPD process for use by school psychologists.

The individualized CPD process described here shares elements across professions and involves five steps (ANA, 1992; Baker, 1981; Houle, 1980; Kaplan, Geoffroy, Pare, & Wolf, 1992; Kathrein, 1990; Rosenfield, 1985). The elements that are emphasized in the CPD process are a problem-solving approach in seeking solutions to skills deficits and to updating skills, self-directedness in launching new learning, and recognition of both internal and external contexts of the individual professional. The five steps are (a) assessing needs, (b) selecting goals, (c) stating objectives, (d) selecting learning options, and (e) making evaluations.

Self-Evaluation of CPD Needs

A needs assessment is a basic aspect of a self-evaluation and is the first step in the suggested individualized CPD process. A school psychologist's needs assessment involves an analysis of professional knowledge and skills relative to NASP CPD skill areas. The CPD skill areas should be considered in conjunction with the current role/function, the expanded role/function, the professional interest, and/or the anticipated career change of the school psychologist. Skills relative to improved performance in one's current position typically should receive priority attention. Skills relative to an expanded role or function in one's present situation and those relative to a future role or career change can be addressed as long-range goals. If the latter two are imminent, they may be a greater priority. Naturally, consideration of one's professional interest is an important additional element in analyzing professional needs.

Table 1 presents a rating scale that can be used for assessing a school psychologist's professional needs. Skill areas are taken from the NASP CPD program (see Appendix V, this volume, for more details about the skill areas). Completion of the scale involves three steps: (a) reviewing skills and knowledge areas relative to NASP CPD standards, (b) rating each area according to predetermined competence, and (c) weighting each area relative to individual needs.

A variety of sources are available for assessing professional competence. Input from supervision is one source. In situations in which supervisory input is not available, peer appraisal is another option. Peer appraisal may be formal or informal. The formal peer group appraisal process involves an organized network of professionals who observe, objectively measure performance, and provide feedback to members. An informal peer group appraisal process involves a group of professionals who get together to critique and share observations about shared needs. Consumer feedback obtained from parent, teacher, and student surveys is yet another means of assessing professional competence. Questionnaires, rating scales, and interviews are additional sources of feedback data.

Directions for completing the needs assessment featured in Table 1 are as follows:

1. Review each specific skill and knowledge area.
2. Record a rating for your knowledge/skill in each area by indicating if your skill/knowledge in the area is satisfactory (S), questionable (Q), or needs improvement (NI) for one or more of the following:
    a. the roles and functions required in your current position;

    b. the roles and functions that would be required if your position were expanded to include new activities and responsibilities;

    c. the roles and functions for a new career or new position;

    d. your own professional interest in an area.

Note: Your skill/knowledge rating is considered in conjunction with your current or expanded role/function, career change and/or professional interest. For example, if you have limited skill or knowledge in a specific area listed in Table 1 but your current job does not require the skill/knowledge, record (S). If your current job does require the skill/knowledge, record (NI).

3. The ratings of knowledge/skill can be recorded by one or more of the following:
    a. yourself (self-assessment);

    b. supervisor;

    c. peer;

    d. consumer (school principal, teacher, etc.).
4. Following completion of the ratings of your skill/knowledge, record "CPD priority weights" to identify the skill/knowledge areas that should be the focus of your CPD activities. First, determine which of the following is most important in regard to improvement of skills — current role/function, expanded role/function, career change, personal interest. Then, for knowledge/skill rated as NI or Q, assign CPD priority weights according to the following scale:

1 = Priority — My immediate CPD goals should definitely include this area.

2 = Relevant — This area may be included in immediate or long-range goals.

3 = Somewhat Relevant — This area may be an appropriate long-range goal.

4 = Not Very Relevant — This may not be an appropriate area for my CPD goals.

Developing and Implementing Personal CPD Plans

Once a determination has been made concerning areas of skill and knowledge needs, the goal selection process begins. Individual ratings of the CPD skill areas determine CPD goals. Areas receiving NI or Q ratings and priority weights of 1 should represent immediate goals. Skills receiving lesser ratings/weights might represent distant or long-range goals. Next, objectives (tasks) designed to meet selected goals are specified. Consideration of learning options or avenues is the next step in the individualized CPD process.

Traditional and Nontraditional Avenues for CPD

Research indicates that participation in CPD activities is an effective means for promoting positive change in professional knowledge, skills, attitudes, beliefs, and performance (Cervero & Rottet, 1984; Cooley & Thompson, 1992; Reschly & Grimes, 1991). A number of learning options or avenues are available. These include traditional and nontraditional methods.

TABLE 1
Knowledge/Skills Rating Scale

	Rating of Knowledge Skill for:[a]				
Skill Knowledge Area	**Current Role Function**	**Expanded Role Function**	**Career Change**	**Professional Interest**	**CPD Priority Weight[b]**
Consultation					
Mental health consultation					
Behavioral consultation					
Educatonal consultation					
Promotion of mental health and learning					
Promotion of preventon of disorders					
Promition of improving educational systems					
Professional inservice					
Skills to enhance collaborative relationships					
Other					
Assessment					
Multifactored assessment

[a] Rating scale for knowledge skills: S = satisfactory; Q = questionable; NI = needs improvement.

[b] CPD priority weights: 1 = priority; 2 = relevant; 3 = somewhat relevant; 4 = not very relevant.

Traditional programs include formal coursework, workshops, institutes, and in-service programs. In situations in which the professional has little or no knowledge to serve as a base for a needed skill, formal coursework is the preferred learning option. Formal coursework has the advantages of guaranteed supervision, guided practice, and feedback (Houle, 1980). Workshops and institutes also provide a means for acquiring needed skills and knowledge, but they may not have the aforementioned advantages (Rosenfield, 1985). In-service programs are the traditional means of providing CPD for school personnel, but they have been severely criticized as ineffective (Spitzer, 1979). Effective in-service programs exhibit cooperatively planned institutional and individual needs, participant involvement, personal and professional relevance, and they provide reinforcement, feedback, and follow-up (Cooley & Thompson, 1990; Truesdell, 1985). Other traditional educational methods are participation in discussion groups and reading professional journals, monographs, books, manuals, and digests (Houle, 1980).

A number of less traditional options are also available. The peer group, a number of individuals organized to meet a shared need, is also an effective learning option (Zins, Maher, Murphy, & Wess, 1988). Their purposes may be varied. As explained earlier, they can be formally or informally organized. The peer group can use a teaching–learning mode in which members teach and learn from one another; a problem-solving mode, in which members focus on mutual problems and use collective problem-solving techniques to resolve the difficulty, or the practice mode, in which members practice a new technique with each other. A fourth option is that of invited guest lecturers. A professional conference can be viewed as an extended peer group meeting (Rosenfield, 1985). Some advantages of the peer group process cited in the literature are increased morale, increased networking, greater familiarity with community resources, increased participation in professional organizations, motivation to continue one's education, and development of professional skills (Zins et al., 1988).

Facilitation, mentoring, and supervision are other less traditional learning options. Facilitators are individuals who can guide continuing professional growth of colleagues by acting either as models, by demonstrating aspects of a skill, or as teachers, by providing instruction on an interactive basis directly related to the professionals' needs. Mentors are individuals who act as counselor/learning facilitators, giving moral support and encouragement. A supervisor could act as a facilitator or mentor (Houle, 1980; Rosenfield, 1985). Another option might be purchased supervision. This could be especially advantageous for those who have no direct supervision but need to develop skill in different areas. Supervisors with different areas of expertise could be hired to accommodate varying needs (Rosenfield, 1985).

The above types of activities can be carried out through a number of technologies, making long-distance learning feasible. Distance education includes the more nontraditional electronic media such as the telephone and speaker phone; taped digests of current literature; audio- and videotapes of lectures, workshops, conventions, and even formal coursework; closed-circuit, cable, and satellite television; computer-mediated communication; and written correspondence study. Research shows the academic effectiveness of distance education to be compatible with that of conventional classroom instruction (Clark & Verduin, 1992).

Self-supervision methods such as recording or videotaping interventions, counseling, and consultation sessions, and later critiquing them according to personal standards of performance, provide additional learning opportunities. Peer groups can be used in this process and in developing checklists to monitor performance in certain areas (Rosenfield, 1985).

Additional means of professional development are supervising interns in the field (NASP, 1992a), and holding a position of leadership in a local, state, or national professional organization. Teaching, research, and program development are other sources of professional development, since all three involve a considerable amount of preparatory study and learning.

Exchange programs, or "trading places," offers another means of professional development. One way to overcome the boredom and the eroding of the sharpness of one's skills is to exchange places with colleagues for a given period of time. This can result in renewed interest, motivation, and new learning (Rosenfield, 1985).

Evaluation

Evaluation is an integral part of ethical professional practice, and numerous reasons have been cited for it (Rosenfield, 1985). The purposes that are most relevant to the individualized CPD process are assessment for accountability and improvements in service, collection of information about strengths and needs, and charting of progress toward goals. By engaging in goal-driven CPD activities that have been developed from the knowledge/skills rating scale (Table 1) and by assessing progress toward or attainment of each, the school psychologist accomplishes all three purposes.

Again, initial development of priorities and goals is the basis for all evaluations in the individualized CPD process. Assessment of goal attainment should follow completion of each CPD activity. Informally charting, graphing, checking, or noting anecdotally such activities as number of professional meetings attended, journals read, workshops presented, and college courses completed are examples of enumerative data that are useful for charting progress toward goals and documenting their attainment. Questionnaires and surveys completed by peers and consumers can provide documentation about improvements in services. Checklists completed by peers, consumers, and/or supervisors can provide feedback about professional strengths and needs that is useful for guiding future CPD plans. Equally important, evaluation in the individualized CPD process should be ongoing, and adjustments should be made as dictated by the circumstances. For example, should a chosen CPD activity prove unsatisfactory in meeting a particular goal, it should be abandoned and replaced with an alternative activity.

Taken collectively, the evaluative data provide the means for certifying CPD participation and attainment of or progress toward, individually selected CPD goals. The need on the part of the profession to monitor CPD activities for maintenance of credentials is addressed by the documentation of completed CPD activities by means of the CPD summary sheet (see Appendix V).

Constraints on CPD Activities

Though obstacles to participation in CPD activities have not been as extensively researched as have been factors that impel it, several deterrents have been identified (Houle, 1980; Scanlon & Darkenwald, 1984; Tucker & Huerta, 1984). The following constraints must be recognized by school psychologists and considered when developing individualized CPD plans.

1. Time. The number 1 deterrent cited by professionals, it includes time away from the job, course schedule, and length of formal coursework.

2. Administrative constraints. Centers around concerns about program quality and/or poor reputation of the sponsoring agent.

3. Expense. Professionals and adults in general cite cost (travel, food, lodging, loss of income while away from work, tuition, registration fees) as the most frequent deterrent.

4. Family. Deterrents such as time away from family, childcare, and family/spousal objections.

5. Disposition. Attitudes and values such as age and family biases, uncertainty, and resistance to chance affect participation.

6. Attitude/motivation. Lack of involvement in the program selection and/or planning, implementation, and evaluation process, as well as program relevance, affects involvement.

Accountability for CPD Activities

Professionalism carries with it the responsibility of maintaining competence. This is done at the level of the individual and through professional requirements to obtain and retain credentials. From the perspective of the individual professional, competence involves the responsibility for maintaining a current knowledge base, preserving sharpened skills and techniques, and providing quality service. From the perspective of the profession as a whole, certification and/or recertification requirements are accountability standards for assuring competence and quality control within its own ranks.

BEST PRACTICES

1. School psychologists must acknowledge their obligation of continually engaging in CPD activities. In a field in which initial training has an estimated half-life of 3–5 years, school psychologists must recognize that preservice training will not take them far. A commitment to lifelong learning is a solution to the problem of continuous skills obsolescence. School psychologists must make such a commitment.

2. School psychologists must approach CPD as a problem-solving activity that must be part of professional practice.

3. School psychologists must not wait until CPD activities come to them, but must plan and organize ways to set up CPD projects that meet their professional goals.

4. School psychologists should systematically assess CPD needs and develop CPD goals, instead of using a hit or miss approach. Effective CPD cannot be obtained by simply engaging in the activities that happen to be provided by an employer or that happen to be available in the local community. School psychologists must continuously monitor their knowledge and skill, identify needs, and develop plans to enhance or increase knowledge and skill.

5. School psychologists should not select CPD activities just for convenience. Rather, activities that will meet goals and promote the most learning should determine selection.

6. School psychologists should consider new avenues for CPD beyond traditional workshops, courses, and in-service. School psychologists should also consider nontraditional activities such as peer support groups, peer supervision, distance education, and computer-mediated communication.

7. Each individual school psychologist should evaluate the effectiveness of a CPD activity, asking the questions: Has the activity really increased my skill/knowledge? Has the activity enhanced job performance? School psychologists who judge that an activity has not been effective in enhancing a skill area should select new options for learning. They should also inform CPD organizers about the effectiveness or ineffectiveness of CPD activities.

8. School psychologists should use problem solving to address constraints to CPD. For example, courses, lectures, or workshops via satellite television or computer-mediated communication provide flexibility in time and schedule. Organizing local peer groups, supervising interns, and engaging in research all promote learning and allow flexibility in time, cost, and schedule.

SUMMARY

Skills erosion, obsolescence, and accountability for effective, competent service provision are recognized concerns among school psychologists. Research shows CPD to be an effective means for addressing these problems. In this chapter the rationale, requirements, and process for CPD of school psychologists were discussed. An individualized, five-step problem-solving procedure was described. Methods, activities, and options for addressing each of the five steps were suggested. Frequently cited constraints on CPD were listed so that school psychologists might recognize and consider each when developing individualized CPD plans. School psychologists must take a proactive stance toward CPD and make it an integral part of professional practice. Such a stance requires a commitment to lifelong learning.

Best Practices in Government Relations

Kevin P. Dwyer
National Association of School Psychologists

> The first step in bringing about change is caring. But caring is not enough . . . One must proceed step by systematic step to mold and assemble the pieces until the whole is positively affected.
>
> Marian Wright Edelman (1987), p. 103

OVERVIEW

- School psychologists are the best trained mental health professionals in the schools
- Children need our services.
- School restructuring and reform will be lost without our involvement.

Most policy makers and stakeholders in educational reform are either unaware of these beliefs or do not understand the role of school psychology in reaching national education objectives. They have not seen the effective and wide range of services that school psychologists can provide to help children reach world-class standards. How can we rectify this gap in knowledge and influence? How can we become more involved in restructuring and reform to make sure that children's social, emotional, and learning needs are met? And how can we make sure that the policy makers understand the value of integrating our services into the restructured school?

School psychologists have the knowledge and skills to effectively advocate for children and for the profession. This chapter will provide basic information on ways in which each and every school psychologist can help shape public policy through involvement in government relations activities at the local, state, or national level.

BASIC CONSIDERATIONS

Within a decade of passage of the landmark Education for All Handicapped Children Act (P.L. 94-142) in 1975, the number of school psychologists more than doubled. Now, another decade later, about 20,000 school psychologists serve 45 million public school children in about 16,000 school systems, at an estimated cost of more than $9 billion a year (Fagan, 1994). Although growth in the profession has been dramatic, our professional standards document the need for another 25,000 school psychologists just to provide minimal educational and mental health services for our nation's children. The cost of the increase nationally is estimated to be about $11.5 billion. How do we persuade the community and taxpayers to pay the additional $11.5 billion for needed school psychological services?

The National Mental Health Association (Koyanagi & Gaines, 1993) reported that only one state in the nation (Connecticut) had the adequate ratio of school psychologists to students, with an adequate ratio being defined as 1 school psychologist to 1,000 students, or 1 to 100 for students identified as disabled and needing special education. The national average of 1:2221 explains why some school systems were given a "D" grade on the national report card of children's mental health services and two states — with ratios of 1:25,000 — received an "F–."

The U.S. Congress Office of Technology Assessment (1986) estimated that almost eight million children have significant emotional or behavioral problems blocking educational success and warranting mental health services within the schools. This means that for every school psychologist employed in the United States there are about 450 students with serious emotional and behavioral problems. This does not include the psychological needs of all other disability groups or children at risk for social, emotional, or learning problems or victims of abuse or crises. The report also stated that almost none of the students with serious emotional problems are receiving needed psychological services. A recent report (McInerney, Kane, & Pelavin, 1992) indicated that only 16% of children with serious emotional disturbance receive psychological services through the Individuals with Disabilities Education Act (IDEA) and only 42% of local public school districts provide any psychological services beyond assessment.

Although these survey and research data are not new to most school psychologists and have peppered the nation's legislative bodies, their impact has been minimal in stimulating a national policy for this critical service shortfall in school-based services. Therefore, research alone will not work. It must be combined with political power (of school psychologists) to influence public policy for the benefit of children, families, and schools.

Poor administrative policies and priorities have made the situation even worse for school psychological services. Existing services are prioritized to serve special education regulations rather than children. School psychologists spend less than one-third of their time providing direct service or consultation services to children's teachers and parents. Most of their time is dedicated to mandated special education eligibility evaluations and procedural meetings, resulting in a lack of service to many needy students. Students placed in special education and those at risk account for a high percentage of school dropouts and adult unemployment. An extensive five-year study of outcomes of special education programs (Wagner & Shaver, 1989) noted that only 36% of students identified as "seriously emotionally disturbed" graduated from high school. After high school age, those emotionally disturbed youth who drop out are much more likely to be unemployed and, according to the study, an astounding 75% are arrested within five years of leaving school.

No one in the community wants these problems to remain unsolved, yet few are willing to support increased taxes to pay for unproven school psychological services programs. Whether it be the local school site-based decision-making committee or the U.S. Congress, service implementation requires proof of improved outcomes. The community will support services that result in increased graduation rates, employment, and independence and reduced violence and drug abuse. Accountability must be improved and information must be conveyed to the right stakeholders, parent advocates, and policy makers.

BEST PRACTICES

Whatever the effort, be it local, state, or national, it is important to evaluate existing and needed resources as they relate to any government relations mission. Several critical factors in this analysis are parallel to the information gathering and analysis that school psychologists use within their professional lives. They include problem identification, goal setting, and analysis of strengths and weaknesses as they relate to a stated mission. School psychologists are experts in team work, measurement, research, and communication. These skills should be utilized in all government relations activities.

Forming a Government Relations Committee

A successful government relations effort requires the time and effort of several people and the commitment of some financial resources. Members of a Government Relations Committee (GRC) must be knowledgeable, dedicated school psychologists who can "think on their feet" and who have the time to share the burden of the numerous tasks required to make the committee work. Because continuity is critical, they must have the ability to sustain the effort over several years.

The tasks of the GRC include:

- Choosing a chairperson.
- Choosing committee members.
- Establishing a vision or mission statement.
- Establishing a network that enhances rapid responses to GRC issues.
- Establishing an information system that increases the association leadership's awareness of the GRC mission and the current critical issues.
- Building relationships with advocates and related professionals.
- Organizing coalitions of education, pupil services, mental health professionals, and other organizations supporting education and children's issues.
- Establishing an information-dissemination system to inform policy makers about the work of school psychologists in the community or state, including highlighting effective programs.

Once you have accomplished the groundwork it is easier to get to the GRC tasks of monitoring local, state, and/or national legislative and agency activities.

Choosing a committee chairperson. The GRC chairperson must be an excellent communicator and facilitator with a strong commitment to the profession and children. The chair guides the committee and the association leaders in communicating with the legislature and agencies. The chair must always follow the guidelines of the approved mission statement and legislative agenda. It is the chair's responsibility to provide feedback to the association's leadership and to the members. Strong public relations, human relations, and cooperative, team-building skills are critical. The chair must be familiar with laws and agency policies that affect the practice of school psychology, education, mental health, and human services. The chair must be an able leader who can delegate, appropriately use committee members' skills, and ensure that committee members receive the information they need to carry out their responsibilities. The committee chair must also use good reinforcement procedures.

When there is a professional staff available, it is imperative that the chair be able to work cooperatively with the association's government relations staff. It is helpful for the association's leadership to establish descriptors for the responsibilities of both volunteers and staff.

Characteristics of committee members.

- Personal Characteristics
    - Action-oriented, assertive personality.
    - Good oral and written communication skills.
    - Strong human relations skills.
    - Interest in or desire to learn the political process.
    - Experience (work or volunteer) in legislative/political process.
    - Personal ties to legislative/political/governmental circles.
    - Willingness to "carry the water."
    - Patience.
    - Knowledge of the legislative process.
    - Enthusiasm and sense of humor.
    - Pride in work and professional role.
    - Involvement supported by spouse and family.
    - Access or geographic proximity to government activity.
- Professional Characteristics
    - Comprehensive knowledge of the practice of school psychology.
    - Representative of professional interests in the organization.
    - Representative of the various geographical and community interests.
    - A client advocate.
    - An advocate of professionalism and program development.
- Work-Related Characteristics
    - Freedom to leave work setting for governmental relations activities.
    - Access to a computer and/or secretarial support.
    - Access to telephone and fax machine.
    - Access to photocopying equipment and materials.
    - Involvement supported by colleagues, supervisors, and administration.

Generating Solutions: Building Coalitions

How can school psychologists prove the merits of their services and gain the support of community leaders to increase these services? The answer requires long-term strategic plans, significant time, dedicated professionals, and financial resources.

A coalition is a union of organizations seeking similar ends. A strong source of information and power, a coalition unifies groups and prevents the fragmentation of forces that share common goals. Building coalitions with groups supportive of school psychological services is critical in getting the message across. The consumers of our services, particularly parents, can become our strongest allies. Other allies with whom to form coalitions include pupil service personnel such as counselors, social workers, nurses, and others who provide services similar or complimentary to those of school psychologists.

Purpose of a public policy coalition.

- Act as an ombudsman.
- Serve as an information source on legislative issues.
- Critique federal, state, and local policy and legislative proposals.
- Propose actions to achieve the desired political action at the federal and state levels.
- Coordinate consensus and unified action among the organizations.

Example of coalition building: School-linked health services. Many communities are forming coalitions among parents, health and education agencies to meet the mental health and other health needs of children. It is valuable to join or interact with existing coalitions which may have a role to play in the community-wide delivery of psychological services to children and their families. Education leadership sees mental health as a "health agency" issue and is frequently relieved to have that agency take the lead in generating solutions.

"Communities Can," a Georgetown University Child Development Center project, sponsored by the Maternal and Child Health Bureau of Health and Human Services and the American Academy of Pediatrics, is a community-based, coalition-building plan being developed in almost every community. It may become a mechanism for change in the delivery of services, including mental health services to children and their families. Being a catalyst for or, becoming part of, a "Communities Can" coalition can ensure that school psychology will remain a viable service among services.

Example of coalition building: Gray Panthers. It is important to broaden the scope of allies and include other groups interested in children.

Sometimes coalitions do make for "strange bedfellows," but it is helpful to have the support of disparate groups to show that your issue has broad-based consensus. In one recent budget-cutting Board of Education meeting, the local senior citizens' chapter of the Gray Panthers came out in support of school psychologists because they believed that violence against the elderly could be reduced by better school-based preventive mental health services. Most community organizations are interested in reducing violence, drug abuse, and vandalism and increasing the employability and social responsibility of youth. These groups may recognize the hidden costs of youth violence and related problems. The National Commission on Children provides excellent data on the long-range costs of neglecting these needs. Community organizations and leaders want to hear about solutions and are consistently supportive of cost-effective intervention plans and services. It is imperative to document solutions and share these with community leaders who have the clout that school psychologists may not have. Building coalitions and allies for school psychological services is as important as establishing a legislative mission.

Monitoring the Legislature and Agencies

Too frequently school psychologists wait to communicate with the legislature and agencies only to respond to a professional crisis or to get a "guild issue" bill sponsored or passed. Although these are necessary activities of a GRC, the outcomes in these and other circumstances will be much more successful when the groundwork has been laid and relationships established between the association, legislators, and legislative staff. Over time these relationships will result in invitations to give input on developing legislation and regulations rather than "putting out fires" after the legislation is drafted.

It would be ideal for the GRC to monitor members from every legislative district, but when funds and dedicated members are limited, the GRC should focus upon specific legislative committees that deal with education, mental health, related social and health services, and — do not forget — the appropriations committee(s)! Legislation without funding is useless. Appropriations committees are usually less sympathetic to increasing services to solve human problems and are generally more responsive to proven money-saving programs and to coalitions that speak with political clout.

To maintain these relationships, your association needs an accurate roster of all legislative and agency officials, including those key staff persons who are the legislator's right hand. Quite frequently the most important persons in the office are the long-term secretaries who screen most incoming communication and who often know the schedule better than any other person in the office.

Agency Contacts

It is advisable to establish permanent professional links with state agencies that have direct and indirect control over school psychological services and the health, education, and social services needed for children and families. Getting on state and local committees that provide advisory support, evaluate programs, and have decision-making power can be invaluable. These committees frequently provide the guidelines for future legislation and the setting of agency policies, rules, and priorities. Being involved in local and state agencies and executive functions can result in having school psychologists appointed to state boards that control education or certification and licensure.

Forms of Communication

Information is a two-way system: Providing information to others is as important as receiving it. Local and state (elected and appointed) leaders should be kept informed about your activities. One way is to include them on your state newsletter mailing list. Other publications and information about effective best practices should be passed on to legislative and agency staff members. And do not forget the governor!

Remember to send any news releases about school psychology to local board of education members and local representatives of your state legislature. Your congressional representatives should also be informed of effective services. Build a file on the legislators' offices to be reviewed when your association seeks those legislators' support. Relationships and follow-up communications are best formed when legislative or agency deadlines are not pressing and staff have time to listen to the valuable information that your association and coalitions can provide.

Legislators also appreciate it when their names and recognition of their accomplishments supporting professional practice and children's issues appear in your publications.

Telephoning. If immediate action on specific legislation is necessary, telephoning can be very effective. You probably will not be put through directly to your legislator, but instead your call may be routed to the Legislative or Administrative Assistant who specializes in education or human service issues. This aide will pass your message on to the legislator for consideration. Call the Capitol Operator at (202) 224-3121 to be connected to a particular office.

Be prepared for the call: Write down important points beforehand and the specific steps you want the legislator to take. Be certain to identify yourself and your location (where you live or are calling from), your professional position (including the names of the schools you serve in the legislator's district), and your purpose for calling. Be prepared to bring the staff person up to date because staff sometimes know little abut the specifics unless their member is on a committee dealing directly with that issue. To help the staff person focus upon your concern, have the bill name and number available. Make sure that the person with whom are are talking can repeat your concern. Use your communication skills, keeping in mind that you are probably speaking to a busy, sometimes underpaid lawyer or professional postgraduate who has several deadlines and many, many important issues on which to focus. Yet, this staff person is usually very interested in your concerns as a constituent. Also, have appropriate questions prepared. Following your conversation, write a "thank you" to the legislator. Mention the staff person's name and any positive comments you can make about the exchange. Appreciation will be remembered.

Telegrams and E-mail. The telegram or mailgram is another quick way to communicate with legislators. It is relatively inexpensive and will usually be sent to the legislator's office within two hours. Although it is quick, it is not as effective as a phone call. Generally, telegrams and mailgrams are best used when you can generate several hundred within a short period of time to show broad support for an issue.

Modern technology provides us with many new methods of communication including the fax machine, voice mail, and electronic mail. Like telegrams, the faxed message may not be as effective as a telephone call, but is useful when a quick response is necessary. The fax is also valuable when it is a specific follow-up to a phone call. Send the fax to the attention of a specific person and remind that person of the previous contact, your detailed identification, the reason for the fax, and the specific action requested. Remember, the name and number of the bill are important ways to jog the memory of the staff person.

Electronic mail (E-mail) is becoming a widely used quick-response method for reaching members of Congress. E-mail addresses for U.S. Senators or Representatives can be obtained by calling their office directly or through the Capitol Operator at (202) 224-3121.

Writing letters. Most legislators' offices use mail as the largest single gauge of public and voter sentiment. Some insiders have noted that many letters to Congress are primarily read for the identifying data and the "side" of the issue the writer is taking on a bill. At the state level, mail is likely to be read with more scrutiny. Personal face-to-face contacts are almost always more effective at the national as well as at the local level. However, a carefully thought out one-page letter which represents an individual's point of view is an effective method of communication. The letter should be clear and simple and express exactly how the measure being proposed will affect the member's constituents. As with the phone call, a letter should refer to a policy or bill specifically by its title and number. Almost all government officials answer their mail.

Timing is important. One can exert greater influence by writing as early as possible before a bill or policy will be voted on and by continuing to correspond with legislators as the bill progresses. If it is possible to identify with a group or cause, do so. Also try to state and document reasons for the position you have taken. A letter simply thanking a member for his or her support is greatly appreciated. Members of Congress who take on difficult issues or who seek additional funds for needed services receive lots of negative mail and your "thank you" can be a significant counterblance.

Send "blind" copies (no cc:) of all correspondence to the national headquarters GPR staff and your state legislative committee chair or state staff. This helps them monitor the level of grassroots activity and to obtain a measure of interest in a particular issue. A sample letter and some pointers are included in this chapter to assist you in corresponding with your state legislator or member of Congress (see Figures 1 and 2).

Visiting. A very effective method of communication is meeting with your legislator either individually or as part of a group. Your objectives are to convey a particular message and also to establish a dialogue. Over subsequent visits, a relationship will develop that can be nurtured through further correspondence and discussions. The member will have a personal awareness of you and your child-centered concernns after such a meeting.

For the visit, know your issues and be prepared with concise "talking points." Be prompt and ready to cover your points in 15 minutes. If possible, learn the legislator's views beforehand. Highlight the legislative issues that concern you and relate their impact on the children you serve. Personalize the issue. Ask for the legislator's feedback — does he/she share your concerns? Try to gain a commitment — what is he/she willing to do? Do not ever threaten or cajole if the legislator does not agree with you. Establishing a good working relationship is important to future contacts. Leave brief written materials as supplemental information and offer to provide further data, if necessary. As soon as possible, send a thank-you letter summarizing your concerns and reminding the official of any actions that he or she agreed to take. Pass along any information you agreed to provide. Finally, offer to arrange for the legislator and his or her staff to visit your work place. This is an excellent way to familiarize them with a "real world" view of the issues faced by school psychologists each day.

Some strategies for successful individual and group visits with government officials are to:

- Make your appointment in advance.

FIGURE 1. Sample letter.

January 1, 1995
8524 Carlynn Drive
Bethesda, MD 20817-4308

The Honorable Connie Morella
U.S. House of Representatives
Washington, DC 20515

Dear Congresswoman Morella:

I am a school psychologist in Montgomery County, Maryland. I serve about 200 students with complex disabilities at Walter Johnson High School in Bethesda. I urge you to support the bipartisan effort to increase mental health services within the schools by co-sponsoring the *Pupil Services Demonstration Act* (H.R. 1234).

A critical component in the total array of services for mental health, wellness, and prevention is school psychological services. School psychologists assist teachers and parents in helping children who are frustrated or angry learn alternatives to violence. At Walter Johnson High, I have worked with counselors and the school nurse to involve staff in supporting peer conflict resolution, social skills training, and anger control. Prevention is a cost-effective service model and the schools are the best place to teach social and behavioral skills. I have enclosed information on a program called "Project Achieve" that demonstrates the cost-effectiveness of the pupil services model. H.R. 1234 will provide the funding to replicate such programs and help meet the unique needs of each community. Please let me know your position on this legislation. I am available at (301) 229-8251 if you wish more detailed examples of successful school psychology programs. Your commitment to the welfare of children is recognized and appreciated.

Sincerely,

Kevin P. Dwyer, MA, NCSP

  - Be on time.
  - Be flexible. If the legislator must cancel, be willing to reschedule.
  - Cancel your appointment only when you have a very good reason and inform the office as early as possible.
- Dress in a businesslike fashion.
- Approach the actual face-to-face meeting in the following manner:
  - Be friendly, polite, and businesslike.
  - Provide those visited with a brief background sketch of your organization and the persons who are present.
  - State the purpose(s) of your visit.
  - Present rationale and opinions for your positions. Be prepared to present clear, relevant facts and statistics.
  - Distribute position papers, resolutions, and other relevant documents.
  - Stress the impact of legislation, regulations, and other governmental/legislative actions on local schools and mental health and human service agencies. Emphasize the impact on children, adolescents, parents, teachers, and the community.
  - Listen to opinions and concerns presented by those visited, giving the legislator a chance to ask questions.
  - Stay on the subject. Be specific about what you want such as seeking support, assistance, sponsorship of legislation, and/or other actions.
  - Speak factually. Answer questions to the best of your ability. If you do not know the answer, say so and promise to obtain any information or data that you do not have readily available. Never promise what you cannot deliver, and be certain to follow up on any promises made during your visit. If you find that you cannot provide the information, make sure you say so.
  - If asked, be ready to talk about the opposition to your position. This can help the official become aware of the political factors in supporting your position and can ready that person for answers to the opposition.

FIGURE 2. Writing elected officials: Basic rules.

- Prepare handwritten letters for all personal communication. Letters from associations and institutions should be typed on official stationery and signed by the appropriate officer, chairperson, or the like.
- Personalize the letter as much as possible. Tell the addressee what position you have and where you live and work. This is especially important if you are a constituent of the person whom you are contacting.
- Begin your letter with the proper salutations, including title, name, and address. The clerk of the state legislature can provide a current list of members and the governor's office can provide a listing of key people in the executive branch. For a list of federal legislators and government officials, consult the various references contained in your local library. Some states have computer software or electronic bulletin boards which contain this information.
- Construct a letter that is clear in purpose and offers concise arguments for your personal position. Attempt to keep your letter to a single page.
- Identify any legislation, law, or regulation by name and number. This will allow staff aides to link your letter to specific issues and record your concerns accordingly. Legislators often refer to such records of public concerns prior to voting on a piece of legislation.
- Provide constructive criticism. Cite the strong points in a bill, law, or set of regulations. Address weak points and areas of omission.
- Offer your personal assistance and that of your association to gather additional information or prepare formal testimony. Such gestures of volunteer assistance can have immediate and long-range impact as legislators and government officials solicit expert opinion on pending legislation and government regulations.
- Make certain that your letter reaches the right person(s) in timely fashion. Do not procrastinate. Your letter is like a vote, and you cannot vote after the polls close.
- Ask the addressee for a response. Most legislators and government officials will acknowledge personal letters. A simple question, inserted in the text of your letter, can ensure this response is more than a routine acknowledgment.
- Approach the addressee in a positive nonthreatening manner. Negative, threat-ridden letters have little impact in the legislative world.
- Identify your organization and the size and nature of its membership. If you are writing on behalf of a branch, state division, or local chapter, be certain that the addressee is aware of the organization, its composition, and the number of persons that it represents.
- Address "blind" copies (no cc:) of your correspondence to key people in the GRC and leadership of your association. This will allow the Government Relations Committee to monitor the breadth and quantity of communication on an issue. Keep a copy of your letters for a personal file. You may wish to refer to a particular letter at some future point or in follow-up correspondence.
- Write a "thank you" letter to those legislators and government officials who act on your behalf. Too many officials only hear from the public and from professional groups when there is a problem or need. They like to hear from you when they have appropriately presented your personal and professional interests.

- Read the nonverbal signals and do not make the meeting too long. Summarize your concerns and arguments, and offer your personal assistance and that of your organization to aid the official in obtaining a better understanding of your professional concerns.
- Thank host/hostesses and close visit. Remember the staff and secretary in the office. They can be key to future contacts.
- Write a thank-you letter to the person(s) with whom you visited, reminding them of your position and enlisting their support.

Testifying. Committee hearings provide an excellent opportunity to present a case for the mental health and educational needs of children and to attract legislative, media, and public support. Spoken testimony by someone knowledgeable in the field of school psychology can be very effective and influential. Most legislators do not have the time to learn about many issues in depth and therefore rely on others to provide the information on which they will make decisions. School psychologists have a perfect opportunity to use their expertise in helping to educate and guide policy makers. In addition, practitioners (by virtue of their experience) are often able to "breathe life" into messages about how policies actually affect children, conveying a greater sense of urgency than these messages might otherwise possess.

Testimony may be presented orally or in writing. Written testimony may be submitted to support an individual's oral testimony or may be proffered on its own to become part of the documentation compiled for a legislative hearing.

Witnesses should know specifically what the committee is considering and what the opposing viewpoint consists of. The witness should be prepared to answer questions from those opposed to the school psychologist's point of view. The witness's statements should be backed up with coalition support, research, and statistics. If your organization is testifying on behalf of several groups, that should be acknowledged. Because politicians think in terms of votes, generally the more numbers you represent the stronger your position will be considered. If others are testifying in support of your position, try to coordinate the testimony prior to the hearing to avoid contradictions, data discrepancies, and redundancies.

The title page of written testimony should be on association stationery and include the name and number of the bill, the name and title of the witness, the name of the legislative body or committee, and the date. The testimony should begin with the name and credentials of the witness as well as his or her organizational affiliation or the group on whose behalf he or she is presenting the testimony. The witness should then:

- Mention the bill number, title, and subject of the hearing.
- Introduce any persons who have accompanied the witness.
- State his or her reasons for supporting or opposing the proposed measure.
- If in opposition, suggest positive alternatives to the legislation in question.
- Provide specific and graphic examples that support his or her position. Personal and professional experience supported by factual data presents a strong case.
- End by summarizing his or her position.
- Make additional information available if so requested.

Developing Your Own Government Relations Program

Activities of a Government Relations Committee. As noted previously, the activities of a successful Government Relations Committee are numerous and require dedicated members willing to work hard for their profession. Both proactive and reactive actions are required; working with a legislator to get new legislation introduced is no less important than working to change legislation already in existence.

There are several "musts" when working as an effective Government Relations Committee. The following can be used as a checklist to ensure that nothing of importance is being overlooked:

- Monitor legislative and governmental activity.
- Establish a working relationship in the name of the profession with legislators and their staff personnel. Present psychology and pupil service viewpoints by engaging in direct lobbying and personal communication, including
  - ◦ Telephone calls and electronic mail.
  - ◦ Letters.
  - ◦ Visits.
  - ◦ Information dissemination (i.e., honorary subscriptions to state and national school psychology publications, reports, news releases and articles, and research data).
- Organize and conduct communication campaigns, including
  - ◦ Letter-writing campaigns.
  - ◦ Telephone contacts.
- Organize and conduct group visits (i.e., "Day at the Capitol") with legislative and government officials.
- Prepare legislation. Work for its introduction and passage.
- Prepare and offer written and/or oral testimony to those charged with preparing relevant legislation.
- Develop and maintain accurate rosters of legislative and governmental officials.
- Conduct government relations training workshops for members.

On the state level, it is advisable to be involved in the administrative process as much as possible. Work to install a member of the profession on official state boards, committees, and task forces concerned with school psychology and the pupil service professions.

1. Involvement with Other Professional and Public/Consumer Organizations.
   - Organize and participate in coalitions of educational, mental health, and related human service organizations.
   - Organize and participate in coalitions of public and consumer organizations.
   - Assist groups in legislative concerns of mutual interest.
   - Enlist support of groups for legislative concerns of mutual interest.

- Prepare and disseminate information, including
  - General public relations pieces.
  - Issue and position papers.
  - Summaries of model programs.
  - General legislative platform.
  - Research documents.

2. Working within the Government Relations Program of the National Association of School Psychologists (NASP).
   - Establish and maintain linkages with your state government relations representatives. Maintain a system of two-way communication.
   - Establish and maintain linkages with the NASP government relations staff. Make sure that you are a member of the School Psychologists Action Network (SPAN).
   - Respond to *all* calls for support and information (i.e., written and/or personal contact with legislators).
   - Participate in NASP Government Relations training programs whenever possible. Keep yourself educated and informed about the legislative process.

Government Relations Committee budget concerns. Because the amount of money available for government relations activities will vary markedly from state to state, it is difficult to produce a sample budget for Government Relations Committee work. However, in developing a budget, each committee should allow for the following expenditures:

- Communications: newsletters, telephone calls, postage, telegrams, and subscriptions.
- Travel: committee meetings, testimony presentation, governmental/legislative visits, NASP training and related activities.
- Supplies and materials.
- Printing and reproduction: brochures, reports, testimony, training materials, and legislative updates.
- Special activities: "Day at the Capitol," training programs, convention activities, and audio/visual materials.

Job description of the governmental relations chairperson. The following should be among the responsibilities of the government relations chairperson:

- Government Data: The chair seeks to become thoroughly familiar with individuals, agencies, and programs operating within the state which can affect local and/or national school psychology and pupil service activities.
- Communications: The chair serves as a link between (a) the agencies of government that shape policies and direct funds within the state and (b) members of the school psychology and pupil service professions. The chair is also responsible for maintaining or appointing a committee member to maintain an effective communications network.
- Public Relations: The chair seeks to establish, sustain, and maximize a continuing dialogue between government contacts and the membership.
- Information Dissemination: The chair ensures that high quality information representing the best interests of the school psychology and pupil service professions is offered to appropriate government sources.
- Decision Making: The chair serves as the expert in his or her state concerning which agency or individuals receive information and the form in which it is best submitted.
- Follow-through: The chair monitors the use of information given to governmental sources and offers suggestions to these sources for possible usage.
- Feedback: The chair strives to ensure that any information generated by governmental contacts is properly received, acknowledged, and directed to NASP government relations staff and interested state and regional representatives.

SUMMARY

All school psychologists can be effective advocates for children and the profession. Successful government relations efforts require the proactive and reactive actions of dedicated members willing to expend the time and effort necessary in bringing about positive change.

School psychologists can influence public policy by monitoring legislative and government activity; communicating with elected officials through phone calls, letters, and visits; preparing and presenting testimony; working in coalition with groups having mutual interests; and preparing and disseminating information on relevant legislation.

ANNOTATED BIBLIOGRAPHY

SPAN Update is a quarterly newsletter produced by NASP staff and sent to all School Psychologists Action Network (SPAN) members. *SPAN Update* provides current information on legislative issues of concern to school psychologists. Available to all NASP members free of charge by calling (301) 608-0500. *Legislative Alerts* will be sent as needed to NASP members when an issue arises that demands immediate attention or action.

Congressional Newsletters and Press Releases are issued regularly by most U.S. Representatives and Senators; constituents can receive them upon request.

Copies of Congressional Legislation can be requested from the document rooms of both houses by subject and bill number. For House bills, send a stamped, self-addressed envelope to:

House Document Room
Room B-18
House Annex #2
3rd and D Streets, SW
Washington, DC 20515
(202) 225-3546

For Senate bills, send the same to:

Senate Document Room
SH-BO4
Washington, DC 20510
(202) 224-7860

The U.S. Congress Handbook contains biographical and statistical information on all members of the U.S. Congress, all committees and subcommittees, the executive and judicial branches, tips on communicating with legislators, and explanations of how Congress is organized and operates. This book may be purchased from Capitol Advantage, P.O. Box 1223, McLean, VA 22101. (703) 734-3266.

The Congressional Record is published daily when Congress is in session and contains the record of floor proceedings plus any additional information inserted by members of Congress on particular issues. The *Record* may be obtained from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

The Federal Register is published daily and contains regulations and legal notices issued by federal agencies. These include Presidential proclamations, executive orders, and federal agency documents required to be published by Acts of Congress. The *Register* may be obtained from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

Education Daily focuses on national, state, and local events pertinent to primary and secondary education. Includes pending court decisions, legislative updates, federal budget charts, and other resources. Published by the Educational News Services Division of Capitol Publications, Inc., 1101 King Street, Alexandria, VA 22314.

Special Education Report covers new laws, regulations, court cases, and funding issues related to educating children with disabilities. Published by the Education News Services Division of Capital Publications, Inc., 1101 King Street, Alexandria, VA 22314.

The Special Educator offers news and analysis of federal laws, rules, and programs concerning the education of disabled individuals. Published by the LRP Publications, P.O. Box 980, Horsham, PA 19044-0980.

Best Practices in Facilitating Professional Effectiveness and Avoiding Professional Burnout

Alex Thomas
Miami University

OVERVIEW

There are an estimated 22,000 to 25,000 school psychologists in the United States (Fagan & Wise, 1994). At a minimum, with each school psychologist having contact with at least 125 students through consultation, assessment, or other direct or indirect service activities, a conservative estimate of 2.5 million students receive some type of professional activity from school psychologists every year. Professional activity is also likely to encompass involvement with these students' families (parents, guardians, siblings, grandparents). Additionally, with increasing emphasis on the delivery of indirect services through consultation, collaboration with ancillary agencies, and greater community involvement regarding social and demographic issues, there is an ever increasing number of people affected by school psychologists' services. There is an individual and collective "spread of effect" which is remarkable and frequently undetected by outcome measures. School psychology represents the most widespread, multifaceted, and available mental health service delivery system for this nation's youth.

The feeling of individual impact of efficacy, however, can often be blunted by the enormity of the problems faced. There may also be frustration with systemic characteristics perceived to provide barriers to more effective services. Additionally, there may be idiosyncratic perceptions of being confined to a rather narrow channel of professional activity despite training and personal choice leading to hoped for expansiveness of service provision.

Most school psychologists enter the profession with high optimism, a hearty work ethic, and genuine enthusiasm for applying psychological knowledge and principles to aid children and their families within the educational enterprise. Some school psychologists maintain that same attitudinal fervor throughout their careers. Some do not. Most, in the course of a career, experience ups and down relative to professional enthusiasm, involvement, and effectiveness.

That school psychologists have an effect on children, families, and systems is not startling news. What is startling, however, is the extent to which professionals in the mental health field, such as school psychology, frequently lose sight of the impact they can have in their respective endeavors. It is often difficult to maintain a positive focus to deliver optimum professional service when there may be personal problems interfering with job functioning, economic and political pressures within the school system, a feeling of futility or uselessness with one's work, or a perception that the organization does not value or use the skills that one has. The frequency, duration, and intensity of such feelings over a long period of time can negatively affect professional growth and effectiveness.

Though there has been no established research linking higher levels of job satisfaction with greater professional effectiveness (presumably, one can be effective and still be dissatisfied with what one does), it is likely that most people would prefer to be rich than poor, healthy than unhealthy, contented rather than discontented, and effective rather than ineffective. As the aphorism states, "Optimists and pessimists are right an equal amount of time but optimists are more enjoyable to be around."

The purpose of this chapter is to review strategies school psychologists can use to maintain or improve an upward trajectory encouraging professional growth and effectiveness.

BASIC CONSIDERATIONS

Job Satisfaction and Professional Stresses

The concept of professional burnout is not necessarily synonymous with low job satisfaction but it is related. Burnout can be defined as feeling emotionally exhausted, feeling a sense of depersonalization or lack of meaningful connection, and having a low sense of personal accomplishment (Maslach & Jackson, 1981). The construct of burnout has existed for some time and comes in and out of fashion as a term related to low job satisfaction, which may also be coupled with an accompanying attitude that may negatively affect a person's nonprofessional life. Huebner (1992) and others (Huberty & Huebner, 1988; Levinson, Fetchkan, & Hohenshil, 1988; Pierson-Hubeny & Archambault, 1987; Solly & Hohenshil, 1986; Wise, 1985) have explored issues of burnout and job satisfaction specifically related to school psychologists.

Huebner (1992) found a strong relationship between burnout and job related stresses such as incompetent or inflexible supervisors, unavailability of resource or testing materials, inadequate secretarial help, lack of contact with colleagues, and feeling caught between children's needs and administrative constraints. Other stresses were noted to be issues related to time management (backlog of referrals, report writing), high risk to self and others (dealing with potential suicide cases, child abuse cases, threats of a due process hearing), and interpersonal conflict (working with uncooperative administrators, conferences with resistant teachers or parents). Among a sample of school psychologists, Huebner (1992) found that one-third met the Maslach and Jackson (1981) criterion for emotional exhaustion, one-quarter met the criterion for reduced sense of personal accomplishment, and almost 10% met the criterion for high sense of depersonalization.

Wise (1985) rank ordered the job stresses identified by survey responding school psychologists (see Table 1). The 35 stress areas were subject to factor analysis and nine clusters were identified. They were, in order of importance:

- Interpersonal conflict (conferences or staffings with resistant teachers, working with uncooperative administrators).
- High risk to self and others (crises situations, due process hearings, child abuse cases, teacher's strike).
- Obstacles to efficient job performance (inflexible supervisors, inadequate secretarial help, feeling caught between child's needs and administrative constraints).
- Public speaking (in-service workshops, parent groups, public speaking engagements).
- Time management (not enough time, backlog of reports or referrals).
- Keeping the district legal (due process, compliance issues).
- Hassles (carrying materials between schools in inclement weather, driving).
- Professional enrichment (inability to keep up with literature in the field).
- Insufficient recognition of work.

Each school psychologist can provide a personal configuration of perceived stressors or barriers to maximum effectiveness based on his or her own circumstance. A conscious acknowledgement of these personal stresses and specific barriers to optimum professional functioning is a first step in developing a plan to minimize them at best, or at worst, place these realities in perspective.

Taking a Personal and Organizational Inventory

Lack of professional morale or feelings of low effectiveness are due to a combination of factors related to personal and organizational characteristics. Personal characteristics are those temperamental or enduring traits brought to all situations including family, vocational, and avocational. For example, are things viewed positively when unfortunate things happen? Put simply, is the glass of water seen as half full or half empty, is the weather described as partly cloudy or partly sunny? Adjectives like "moody," "cheerful," "energetic," "phlegmatic," "unhappy," "depressed," "positive," "excited," and so forth, may be consistently used to describe personalities independent of context. There are people who bring energy and verve to the most difficult circumstances and those who bring a sullen defeatist attitude to the most positive circumstances. It is important for an individual to know what his or her own tendencies are. There will probably always be people who say they are "burned out" and spend much time bemoaning circumstances conspiring against them. In some instances, however, colleagues would argue that being burned out is impossible for these people have never been on fire. Others can, with an advantageous situation, find reasons to complain and find fault ("Have a nice day!" "No thank you, I have other plans.") Yet some people are capable of making the best of any situation, however adverse it may be.

A large component of professional growth and effectiveness is the personal orientation that is brought to any endeavor. Each individual needs to understand his or her own nature and predisposition independent of organizational or environmental circumstances.

Organizational characteristics are those inherent within a school or district unit. Even the school psychologist of the century may not thrive in some organizational climates. A competent, well-trained school psychologist may, nevertheless, be poorly compensated, not released for professional development activities, forced to do routine assessments, and offered little administrative support within their district. In an adjoining district, a school psychologist of less distinction may be well compensated, allowed significant freedom for professional growth, and have the possibility to engage in a variety of role functions. Some of the factors influencing the specific organizational climate, which are independent of personal characteristics, would be size of the district, the type of supervision provided, the organization of special

TABLE 1
Ranks and Means of Stressful Events for School Psychologists

Stressful Event	Rank	Mean
Notification of unsatisfactory job performance	1	7.1
Not enough time to perform job adequately	2	6.6
Potential suicide cases	3	6.5
Working with uncooperative principals and other administrators	4	6.4
Feeling caught between child's needs and administrative constraints (i.e., trying to "fit" a child into an existing program)	5	6.3
Threat of a due process hearing	5	6.3
Lack of appropriate services for children	7	6.1
Child abuse cases	8	6.0
Incompetent or inflexible "superiors"	8	6.0
A backlog of more than 5 reports to be written	8	6.0
Working in physically dangerous situations (e.g., gang-rule high schools)	11	5.8
A backlog of more than 10 referrals	11	5.8
Pressure to complete a set number of cases (e.g., you must test at least 100 children a year)	13	5.7
Conferences or staffings with resistant teachers	14	5.6
Conferences or staffings with resistant parents	15	5.4
Teacher dissatisfaction with your recommendations	16	5.2
Report writing	17	5.1
Conducting in-service workshops	18	5.0
Keeping your district "legal" (i.e., in compliance with federal, state, and local regulations)	19	4.9
Public speaking engagements (e.g., P.T.A.)	20	4.8
Insufficient recognition of your work	20	4.8
Telling parents their child is handicapped	20	4.8
Lack of consensus in a staffing	23	4.6
Inadequate secretarial help	24	4.3
Being told that you "have it easy" by classroom teachers	25	4.2
A change in the schools or districts which you serve	26	4.1
Lack of contact with professional colleagues	26	4.1
Screening bilingual children	26	4.1
Conducting parent groups	26	4.1
Lack of availability of appropriate assessment materials	30	4.0
Impending teachers' strike in your district	31	3.9
Supervising an intern or school psychology graduate student	32	3.5
Keeping up with current professional literature	33	3.4
Carrying testing equipment around in unfavorable weather conditions	34	3.1

education and pupil personnel services, and the district's history and philosophical orientation. School psychologists need to understand the organizational unit in which they are embedded independent of their own personal characteristics. Often the quality of the setting is unrelated to the abilities of the school psychologist.

In addition to stable personal and organizational characteristics, time can bring changes to professional outlook. Discussing stages of development in the original manuscript for the Vineland Social Maturity Scale, Doll (1953) outlines the dietary stages of life which can be adapted to the stages of career as well (see Table 2).

TABLE 2
Stages of Life and Career

1. Milk.
2. Milk and bread.
3. Milk, bread, eggs, and spinach.
4. Oatmeal, bread and butter, apples, and an all day sucker.
5. Ice cream soda and hot dogs.
6. Burger, french fries, coffee, and apple pie.
7. Sirloin tip, baked potatoes, creamed broccoli, fruit salad, cherries jubilee, Brazilian coffee.
8. Pate de foie gras, wiener schnitzel, potatoes Parisienne, egg plant a l'oppera, demi-tasse and Roquefort cheese.
9. Soft boiled eggs, toast, and milk.
10. Milk and bread.
11. Milk.

Note. Adapted from Philadelphia Rotary Club as cited in *Measurement of Social Competence* (p. 27) by E. A. Doll, 1953, Circle Pines, MN: American Guidance Service.

School psychologists need to acknowledge in which stage their professional careers are. The goal is to spend most, if not all, of one's professional career in a nutritious stage with a well balanced diet.

A Personal Inventory

My own personal inventory of practitioner stresses encompassing organizational and personal characteristics included, in no particular order:

- Interpersonal conflicts with one or two ancillary professionals that persisted despite earnest ameliorative efforts.
- Too many winter days with travel to three or more locations (which meant I was always chilled).
- Schlepping "stuff" between buildings.
- Discovering, after heroic efforts to be at a specific school at a specific time, that the youngster to be seen was absent or on a field trip.
- The need to be poised at the most vulnerable time of the day for me (late afternoon staff meetings or conferences).
- Due process procedures that appeared more akin to "endless process."
- An increasingly adversarial nature of first meetings due to the influence of the media and well-meaning advocacy groups.
- What I saw as time wasted with meaningless assessments to meet rigid state mandates.

It is important for school psychologists to conduct an inventory of the personal and organizational characteristics that contribute to high and low levels of professional satisfaction and effectiveness. If there is minimal enjoyment or satisfaction, little sense of wonder or discovery, or low or nonexistent feelings of efficacy, a need exists for developing a realistic plan to deal with these conditions.

Expending energy on problems over which one truly has no control is pointless. If an individual has attempted to positively address a source of stress and not been successful, there is no need to create more discomfort by worrying about the inability to deal with the stress. A saying goes "In the desert, it is dry and hot." The implication is that being thirsty and hot is an expected condition of being in a desert so why complain. School psychologists would do well to identify their own professional deserts, that is the barriers to their professional growth and effectiveness, and determine which ones are workable and which are not. Diligently work on those that are workable. However, it is quixotic and a sure path to frustration to continually confront situations when there is no likelihood of success.

Once personal and organizational strengths and weaknesses have been assessed, you can develop a plan (a practitioner's Individualized Effectiveness Plan) for yourself which includes current levels of performance, measurable goals in areas of assessed need, and planned interventions to achieve those goals.

BEST PRACTICES

Maintaining or facilitating professional growth and effectiveness requires a conscious effort much like maintaining interpersonal relationships, maintaining or developing skill at a sport, or developing and maintaining expertise at a hobby. One cannot rely on serendipity. Paraphrasing a sports or work aphorism, when a person complimented another on being lucky enough to enjoy what she did and also lucky to be very effective at it, the response was: "The harder I work at it the luckier I get." Rarely does anything of value come easy.

It is important to develop a personal individual development plan which incorporates the current level of professional effectiveness, describes the personal and organizational barriers to increased levels of effectiveness, and outlines a plan to increase professional effectiveness. Any implemented plan can also facilitate attaining continuing professional development requirements for state certification and be credited for NCSP renewal. The following areas of attention should be considered in formulating a professional and personal development plan.

Maintaining Physical and Psychological Health

Obviously, one's physical and psychological health extends to all life activities, including vocational. Maintaining physical health means taking care of one's body with respect to nutrition and exercise. Those likely to be reading this already know resources related to exercise and nutrition and already know the importance of maintaining the body. It is unlikely that the more subtle best practices suggestions that follow would have any merit if this basic dictum is not considered.

Psychological health related to employment means maintaining a delicate balance between the realistic possibilities of using one's training and individually developed skill to help others while simultaneously not developing unrealistic expectations of either the impact to be made or the appreciation of others for such expenditure. Admittedly, this is a delicate balance. If you become discouraged and disenchanted, then your personal effectiveness may diminish. On the other hand, falsely high expectations can lead to disappointment in the outcomes.

Related to personal characteristics is the notion of the impostor phenomenon (Harvey, 1985). This construct refers to the psychological anxiety created by high-achieving professionals who feel that they have arrived at a certain level of perceived expertise by subterfuge and that, at any moment, someone is going to find out they are a fraud. The continued feeling of anxiety accompanying professional activities is a function of the impostor phenomenon: that at any moment the "high-achiever" will be unmasked and announced as an impostor. These high levels of self-expectation do equate to high professional productivity but also to increased stress. However laudable the goal to be all things to all people, it may be unrealistic to maintain quality consultation services to scores of teachers, complete 75 or more quality assessments in a year, implement and monitor 50 yearly interventions of high quality, participate actively in curriculum and other system level committees, be sought for counsel by principals and other administrators, participate actively in school related social activities, conduct research on district problems, while simultaneously maintaining a fulfilling family and civic life.

Peer Support

It is possible to feel isolated and alone even in a large system, to feel as if you are the only person having to deal with an angry teacher, uncooperative administrator, belligerent colleague, immovable school system, overwhelming number of referrals and reports yet to be written. For those school psychologists who practice in rural or small suburban districts and have no colleagues, the sense of isolation may be even more dramatic.

A peer support group can assist in providing a sense of camaraderie and connection. It does not have to be formal. It can be a group of professionals who meet on a periodic basis to talk about common problems, discuss professional developments, share stories or anecdotes, and provide a supportive environment for each other regarding professional endeavors. At a minimum, peer support could mean monthly luncheons or a "happy hour" with colleagues, or even being part of an electronic network. It could extend to weekly formal meetings with established agendas, presentations, and minutes. Additional perspectives and specific details for establishing a peer-support group can be found in Zins, Mayer, Murphy, and Wess (1988), who also list key elements of establishing these groups (see Table 3).

Involvement in Professional Associations

Professional association involvement is important in maintaining a sense of professional identity, providing opportunities for continuing professional development, and communicating contemporary information about political and professional activities related to the discipline. Involvement in these associations can be viewed on a continuum from membership (receiving notices of conferences and various publications) through attendance and participation at association meetings, to committee membership, to election to the executive board or as an officer.

There are associations for school psychologists at the international, national, and state levels. Some states are divided into regions and regional association membership is available which may provide some of the peer-support activities referred to previously. In larger states, the regions may be further divided into county or city associations. Within most associations, there are numerous possibilities for involvement that would coincide with an individual's particular interest or skill. Most associations have committees dealing with professional issues (e.g., children's services, special education), legislative activities (e.g., legislative or governmental affairs), or organizational maintenance (e.g., membership, elections). In addition, there is ample opportunity to participate in communications (e.g., public relations efforts, association newsletter) or professional devel-

TABLE 3
Key Elements of an Effective Peer Support Group

- Establish a nonthreatening, supportive environment and norms that encourage participation and openness.
- Involve all participants in agenda setting.
- Identify a highly relevant, broad range of topics for meetings.
- Build member commitment and enthusiasm.
- Maintain group camaraderie, trust, and support.
- Facilitate a networking process that continues outside of group meetings.
- Vary learning formats.
- Select members who share common professional goals.
- Rotate leadership.
- Include participants who are diverse in terms of employment settings, educational backgrounds, and professional experiences.

Note. Adapted from "The Peer Support Group: A Means to Facilitate Professional Development" by J. E. Zins, C. E. Mayer, J. J. Murphy, and B. P. Wess, 1988, *School Psychology Review, 17*, p. 144.

opment (e.g., annual conventions, workshops) activities.

Most school psychology associations maintain a regular newsletter containing professional information, notices of future meetings, and discussions of contemporary issues. Associations provide the opportunity to place individual endeavors in a larger context and to influence local, state, or national policy in areas where a practitioner may have a particular interest. Associations provide the opportunity to work collectively on issues where there may be individual frustration. This collective effort when successful allows individual endeavors to be seen in a more positive context.

There are also professional and non-professional groups in related fields such as parent teacher associations, learning disability or autism groups, and so forth. Association involvement can increase a sense of efficacy, provide some peer-support opportunities, and also be a source of personal and professional friendships.

School and Community Involvement

It is a rare occasion that a child is referred because of a long attention span, inordinate scholastic persistence, or achievement greater than ability would dictate. By the nature of the discipline, and despite earnest efforts to promote a preventative model of service delivery, most students seen and services provided are based on the perception or the reality of problems. This can contribute to an unrealistic view of the schools, the community in which the schools are located, or the larger society in which the community is embedded. Just as involvement in the local or school community is perceived as healthy for families and for children, such involvement can also promote positive outcomes for professionals.

Being a coach or club advisor for a school group can provide access to students, parents, and teachers whom the school psychologist may never meet under professional circumstances. Not only can these contacts provide a positive spread of effect in activities more directly related to professional roles, but also they provide an opportunity to view a different side of the school system. Volunteering to be part of a school committee, to chaperone for a field trip or student venture, or even to substitute (where possible) for a teacher taking a professional development day can reap unforeseen benefits in improving access to students, teacher rapport, parental acknowledgment, and administrative support. Being seen in a non-psychologist light can also lead to vulnerability and establish a different relationship with staff who may be accustomed to seeing the psychologist in a specific role. Even participating in school sports pools or joining with the staff in their lottery ticket purchase can increase the sense of community with a school and certainly provide topics of conversation removed from routine business. Although these frivolous or non-focused conversations may seem irrelevant, they may lead to greater receptivity and satisfaction when business is discussed.

A perennial question emerging in most introductory role and function classes is whether the school psychologist is a guest in the school or an integral part of the school family. Whatever the circumstances the feeling of distance can be minimized with increased participation by the school psychologist within the school community. The chapter by Kelly (this volume) on school-oriented public relations activities has numerous suggestions on how this can be accomplished. By initiating these activities, the school psychologist may come to be viewed as part of the school family, an unintended, positive benefit.

Within the community, there is also ample opportunity to participate depending on your interests. Joining and participating in service clubs, offering to write monthly articles about timely topics for the local paper (most communities have free papers advertising local businesses and providing information on local events), or volunteering for a community activity increases visibility within the community and, like activities discussed within the schools, has potential unintended benefits.

Just as the family's involvement in ongoing community events can be important to their health and the health of the children, so does the school psychologist's involvement in the life of the school and community portend greater receptivity for services that he or she has to offer. Community support is good for personal morale and effectiveness and can bolster the often-voiced desire of school psychologists to expand their professional roles.

Using Positive Professional Metaphors

The use of cognitive reframing can affect the delicate relationship between thought and reality. Given the circumstances with which many school psychologists deal, it is easy to view the world with jaundiced eyes and skeptical ears. If metaphors of war and battle are used to describe activities — "on the front lines," "in the trenches," "escaped that bullet," "won that battle" — then that school psychologist views his or her role within a war-like context. Even natural activities can be shaded and seen in this harsh way. Examine the metaphors used when working within schools. If negative metaphors like those involving war or drowning (e.g., "up to the neck in alligators," "throw me a rope," "going down for the last time," "sink or swim") permeate the conversation, then it might be time to review personal and professional descriptions.

Reframing will not change the objective reality of a situation, but it may change an individual's perspective on it. Try viewing service delivery as the preparation of a gourmet meal: Things must be ready at the same time, some dishes need to be on the back burner, some do not turn out as planned, some are over-cooked, some half-baked, and some need more time to simmer. Or service delivery can be turned into an investment or financial metaphor: need to invest more in this project, must look at assets and liabilities, need better returns for the investment. The school psychologist as gardener is another metaphor (e.g., nurturing, needing more sun or water to thrive, prune back for optimum growth).

Initially, the metaphors used may describe one's feelings but eventually they shape one's thinking as well. Maintaining maximum professional effectiveness requires as positive an outlook as possible within the circumstances, and use of language can assist in shaping that reality.

Professional Activity That is Prized

Most everyone has a prized project that they would like to undertake but often feel there is not the luxury of time for such indulgence. It is vital for school psychologists to have an ongoing project that is not routine and which represents a potential professional service. Even though this often involves risk-taking, it can enhance overall satisfaction.

This volume of *Best Practices* contains numerous topics and offers annotated bibliographies where additional resources can be found within each topic. In every setting there is usually a receptive teacher and often a receptive school where initiatives on your part will be appreciated. Organize a parent program or a group on an important topic for students or teachers, conduct a research study to answer local questions, or develop specific expertise and experience with a population with which you have had interest. Make it a goal to spend part of each day, if only 5 minutes, immersed in the topic: to read about it, talk about it, plan it, or implement it. If you do not find the time for this activity, you must make the time.

Maintain a Sense of Humor and Perspective

The practice of school psychology is a serious business and can be fraught with numerous frustrations. Maintaining a sense of humor and perspective while delivering professionally competent services is essential for continued professional effectiveness. Whether it is the funny things that students say during interviews or assessments, the seemingly Catch-22 administrative or bureaucratic dictums by state or school policies, or the sometimes absurd expectations of service desired by colleagues, an element of humor and a heightened perspective can usually be found. Maintaining a degree of involved and committed distance is facilitated through maintaining a sense of humor and perspective.

Activities to facilitate humor might include keeping a log of favorite student responses, a top-10 list of frustrations or impossible requests for service, or a doodle sketch pad of caricatures for the artistically inclined, or develop creative acronyms. I can recall inadvertently asking a student "what is the thing to do if you cut a finger that belongs to someone else?" That experience initiated an off-beat interest in creating very brief assessment techniques by combining several questions. Such activities would provide good conversation among colleagues or be a welcome addition to an association newsletter.

Such humorous diversions in no way detract from the seriousness of professional activities but can help place daily frustrations and stresses in perspective. Humor, it is important to note, should never be used to disparage people. Humor, however, used optimally, assists in gaining perspective and maintains social contact without diminishing quality service delivery.

Taking the Larger View

In many places, a frustration inherent in contemporary service delivery is the systemic expectation of making a binary (yes/no, eligible/not eligible) decision regarding students. There is no assurance that being or not being in a specific program would be good for the child. The line of children to see will always go out the door and extend down the hall. However fast school psychologists consult, test, or assess the line goes on.

Decisions and procedures are established at the national, state, school district, and school levels to provide parameters within which services are provided. Although the service delivery level where most psychologists operate is the most important level of decision making, latitude at that level is limited by these policies and procedures. Because the strictures of these parameters can be frustrating, it may help to extend one's point of view. For example, having to do automatic intelligence testing for re-evaluations of high school students who have received similar assessment five times over 12 years can be inordinately frustrating as well as futile. Such frustration can be attributed to the notion that it is a federal regulation, that decisions were made higher up the professional hierarchy or food chain, and that they have filtered down through state and local systems in the form of regulations and policies. As long as school psychologists *only* deliver direct services, then their influence on policy that guides and informs direct service delivery will be limited. For example, administration of an intelligence test for re-evaluation is not specifically stated in any federal regulation. These regulations are interpreted by state and school district officials as a requirement. This interpretive rigidity may also apply to retention policy, structure of special education services, use of corporal punishment, or other programs for students experiencing school problems.

School psychologists can work individually and collectively at policy levels to eventually impact practice at the most important level, direct service delivery. This is not only an issue of empowerment but also one of morale. If an individual has no control of his or her destiny, then it becomes inevitable to feel robotic and to lack a sense of professional efficacy.

Whether the individual school psychologist feels frustrated about the retention policy in the district, the lack of programming options for children with specific learning characteristics, or the manner in which the district chooses to use discretionary federal or state funds — all those decisions made apart from the service-delivery level yet certainly affecting its outcome — these barriers at other levels of the professional food chain must be identified and dealt with. The chapters by Curtis and Stollar (this volume) on system-level consultation and by Dwyer (this volume) on influencing public policy can aid in suggesting strategies to assist in thinking and acting systemically.

SUMMARY

Maintaining quality professional services requires that each school psychologist inventory the personal and organizational characteristics that are barriers to a heightened sense of effectiveness and professional growth. Most school psychologists know what to do in this regard but the key is to actually develop and consciously work toward implementing activities that promote growth and effectiveness, and by implication, avoid professional burnout.

These activities include maintenance of both physical and psychological health, involvement in the professional and school communities, ongoing peer-support in some form, awareness of the language used to describe activities and frustrations, maintenance of a sense of humor and perspective, and thinking systemically as well as individually.

Anyone trained in a helping profession is aware of the concept of intervention adherence. Most school psychologists can identify specific personal and organizational barriers to optimum professional effectiveness. It is further likely that there are specific activities that have the potential to overcome these barriers. Just as losing weight is simple (eat less, exercise more) or raising responsible children is simple (provide love, structure, and consistency) school psychologists may similarly know what can be done to promote professional growth and effectiveness. The challenge is to integrate these activities into a daily routine and to adhere to the plan.

ANNOTATED BIBLIOGRAPHY

School Psychology Associations

There are school psychology associations at the international, national, and state levels. Some states have regional associations. To gain more information about these organizations, contact:

International School Psychology Association: ISPA, Hans Knudsens Plads 1 A, 1. tv., 2100 Copenhagen 0, Denmark.

National Association of School Psychologists: NASP, 4340 East West Highway, Suite 402, Bethesda, MD 20814.

Division of School Psychology (Division 16), American Psychological Association: Division 16 Member Services, APA, 750 First St., NE, Washington, DC 20002.

State School Psychology Association: contact NASP, Membership Services (address above), for the specific address of your state association.

Regional School Psychology Association: contact your state association president or the state association office.

Publications

Ohio School Psychologists Association. (1993). *Hermobilia*. Columbus, OH: Author.
This is a collection of whimsy related to school psychology: over 150 cartoons, flow charts, humorous articles, and drawings. Most were done by Herm Zielinski whose work has been featured in the *Communiqué* and in Sattler's *Assessment of Children*. Available (until July, 1998) as nonprofit service ($8 check covering postage and handling) from the Ohio School Psychologists Association, 750 Brooksedge Blvd., Westerville, OH 43081.

Zins, J. E., Maher, C. E., Murphy, J. J., & Wess, B. P. (1988). The peer support group: A means to facilitate professional development. *School Psychology Review, 17*, 138–146.
The peer support group is described and illustrated with a case example. A description of goals, structure, and composition, activities, and professional outcomes are outlined. Though it is likely that most school psychologists would find it impractical to implement this model in total, it is an excellent resource for considering the advantages, structure, and prospective barriers in developing peer support activities.

Best Practices in Supervision of Interns

Jane Close Conoley
Theresa Bahns
University of Nebraska-Lincoln

OVERVIEW

Though largely unexplored in the research and conceptual literature of school psychology, the role of supervision of psychology interns is of vital importance for the welfare of clients and the welfare of the profession (Ross & Sisenwein, 1990; Zins, Murphy, & Wess, 1989). Supervisors must be concerned about their interns' knowledge and behavior in terms of ethics, competence, and personal functioning (Lamb, Cochran, & Jackson, 1991). In consequence, this is a very complex and demanding role.

Supervision of interns is conceptualized from a number of perspectives (Bartlett, 1983; Blocher, 1983) and may be seen as a sequence of learning objectives or as a developmental sequence of self-perceptions and other perceptions by the supervisor and the supervised (Stoltenberg & Delworth, 1987). In addition to conceptual understandings, the process of supervision is regulated by the National Association of School Psychologists (1992, 1994) and the American Psychological Association (1981, 1992).

However one defines and implements the process, supervision is a key factor in the construction of critical attitudes and skills in new professional psychologists. Despite its importance, most supervisors report limited academic training in supervision or access to peer supervision (Zins et al., 1989). herefore, an important first step in exploring the supervisory process is for supervisors to attend to their own skills, knowledge, and vision for the supervisory relationship.

Part of this self-assessment deals with developing a theoretical model to guide supervisory behavior; another deals with constructing standards of behavior between supervisor and supervised; and finally, part has to do with creating a plan to engage the intern in complex ethical decision making in regard to the complicated problems facing school psychologists in the 1990s.

This chapter will consider the needs of the supervisor, the intern, and the client from a number of perspectives. Supervision is carried out with overlapping responsibilities to the intern, the host training context, the intern's academic program, and the clients. It is not a role to be taken without careful study and continuing refinement of skills. A first step for supervisors is to identify which existing supervisory model is closest to their theoretical orientation and to begin a process of study.

MODELS OF SUPERVISION: BASIC CONSIDERATIONS

There are several models of supervision that are based on various theoretical orientations: psychodynamic, client-centered, behavioral, and developmental. Brief comments on each of the models follow.

Psychodynamic Supervision

The primary focus of psychodynamic supervision is on supervisees' learning to use themselves effectively in helping relationships. This is accomplished primarily by concentrating on the dynamics of the supervisory relationship to monitor constructive or destructive ways of reacting to others. It is assumed that understanding the relationship dynamics of the supervisor and supervisee will generalize to understanding the dynamics between supervisees and their clients.

Supervisors must build a working alliance with their interns. This alliance is based on a willingness to work together to improve the effectiveness of the supervisee. Proponents of this model suggest that any unresolved personal issues of supervisees and supervisors are major impediments to development and growth (Thorenson, Miller, & Krauskopf, 1989).

There is little research to support this model. The danger of creating therapeutic rather than supervisory interactions has been suggested (Doehrman, 1976). However, national studies of clinical psychologists state that between 2% and 60% of the respondents admit to working sometimes when they are too distressed to be effective (Farber, 1985). Such findings suggest the need to train interns to reflect upon their own issues as a necessary ingredient to competent professional functioning.

Client-Centered Supervision

Growing from Rogers's (1958) seminal work, client-centered supervision seeks to establish conditions between supervisor and intern that mirror the conditions that are necessary for effective psychotherapy. The therapeutic conditions of psychological contact — congruence, unconditional positive regard, empathy, and warmth — are the necessary and sufficient conditions in any relationship based on increased self-exploration. Interns must be taught how to create and communicate each of these conditions in their relationships with clients. Interns' professional development depends on the supervisor's skills in creating and communicating these therapeutic conditions.

Tapes, modeling, role-plays, and live demonstrations are often components of client-centered supervision. Personal therapy is seen as a very important way of increasing supervisees' expertness in interpersonal relationships. Research indicates that supervisors must teach specific techniques and skills as well as facilitate a supportive environment to increase supervisees' effectiveness (Forsyth & Ivey, 1980).

Behavioral Supervision

Proficient performance is based on learned skills. Supervisors must teach appropriate behaviors and extinguish inappropriate ones. Each intern's job can be broken into identifiable tasks with associated skills. The supervisor should use the same behavioral principles with the intern as are used in all professional interactions with colleagues and clients (Delaney, 1972).

Mutual assessment of skill deficits and strengths are followed by a shared commitment as to the steps to be taken to meet measurable goals. Frequent feedback is provided regarding current progress toward attainment of goals. Supervision is conducted through an individualized contract of specific behavioral goals and identification of the means for attaining these goals. The key steps of supervision are as follows: (a) Establish a relationship between supervisor and supervisee; (b) assess skills; (c) set supervision goals; (d) generate and implement strategies to accomplish goals; (e) evaluate strategies and generalization of learning.

The failure to provide feedback and provide for remedial activities is often the basis for ethical complaints between supervisor and interns (Freeman, 1985; Keith-Spiegel & Koocher, 1985). A strength of the behavioral approach is the demand for clear communication and careful monitoring of skill development.

Developmental Supervision

Supervisees pass through predictable stages of levels on their way from being apprentices to masters (Stoltenberg & Delworth, 1987). Beginning supervisees lack confidence and are dependent on the supervisor for advice and direction. At this early stage, interns may be more concerned about how to do things the right way and not have much insight into their own behavior or impact.

With some experience, many interns begin to experience a conflict between dependence and autonomy. Thus, feelings of confidence are quickly replaced by feelings of being overwhelmed. Supervisors and interns may have disagreements over the right way to handle situations.

Eventually a firmer sense of identity and self-confidence evolves. The intern becomes more tolerant of differences and is increasingly more flexible in choosing approaches to solve problems. In addition, the supervisee seeks help and advice without feeling too dependent on the supervisor.

Excellent supervisors change their behaviors (from advice giving to support) according to the needs of their interns. They do not overreact to predictable conflicts or testing behaviors and are patient with interns' early feelings of helplessness.

Synthesis

The personal style of the supervisor and intern, the supervisor's and the intern's characteristics, and previous experiences with supervisors will all interact in choosing a particular model of supervision. The best supervisors may be those who have been able to manage a flexible blending of the above perspectives. They provide structured resources for interns in terms of goals and learning experiences while making sure to emphasize the personal impact of the intern. The personal impact of the intern is a function of his or her ability to carry interventions through to successful completion through careful planning, evaluation, and coordination of the efforts of other persons involved. Experience has indicated that powerful technologies are wasted if psychologists cannot gain the investment of staff members and families in their intervention efforts. Furthermore, the intensity of the supervisory relationship demands that the supervisor have some framework to use in sorting out dynamics.

BEST PRACTICES IN THE SUPERVISION OF INTERNS

Assessment of Supervisory Skills

In addition to meeting the requirements for being a supervisor from the relevant professional organizations (e.g., school psychologists with continuing credentials; doctoral, licensed psychologists), supervisors should reflect upon their own supervisory skills and experience in order to prepare for the supervisory role.

Appendix A is a suggested format for rating the supervisor's skills. Completing this assessment may provide supervisors with some important learning goals and information about blind spots in their own behaviors.

For example, the supervisor's comfort with allowing independence among interns is very important to analyze. Interns in the Nebraska Internship Consortium in Professional Psychology (Kramer, Conoley, Bischoff, & Benes, 1991) often describe supervisors as too laissez-faire (i.e., tending to allow for too much independence) or as too controlling. Given the developmental issues raised above (Stoltenberg & Delworth, 1987), it is vital that supervisors be aware of their general stance toward the autonomy of the intern and the ways this stance may be modified according to intern or client situations.

Evaluating Supervisee Skills

A successful supervisor must develop a number of strategies for evaluating the level of intern skills so that appropriate teaching plans can be made and assessment activities accomplished. The critical issues for the supervisor to investigate are as follows.

1. *Competence.* Does the intern have the necessary skills, techniques, and abilities to take appropriate action? Psychologists must be expert in implementing and interpreting numerous assessment procedures, performing direct interventions with children and their families such as counseling and behavior modification, and indirect interventions (e.g., consultation, research, and evaluation).

2. *Emotional awareness.* Can the intern use his or her own emotions and reactions to understand others? Supervisors must target interns' communication skills, interpersonal relationships, and personal stability as potential areas for change if problems are apparent.

3. *Identity.* Does the intern develop a consistent way of thinking about problems and planning actions?

4. *Respect for individual differences.* Does the intern make an active effort to understand and appreciate cultural or ethnic (or other) differences? Is basic respect present for alternative lifestyles and choices?

5. *Purpose and direction.* Can the supervisee formulate plans, identify short- and long-term goals, and map progress? Research training should have had the outcome of preparing interns to complete $N = 1$ studies, collect data, and evaluate outcomes. Intervention or assessment without outcome-based evaluation is questionable practice.

6. *Autonomy.* Can the supervisee make choices and decisions independently? Is there an appropriate degree of self-management?

7. *Ethics.* Are ethical issues, values, and standards integrated into practice?

8. *Motivation.* Is the intern internally motivated, finding work rewarding and meaningful?

Making informed judgments along these dimensions will demand that the supervisor meet individually with the intern, observe the intern's professional functioning, and collect evaluations from others who are directly involved with the intern. The evaluation instrument used by the Nebraska Internship Consortium in Professional Psychology is reproduced as Appendix B. This device is completed twice each year. The completion of the instrument serves as a way for the supervisor and intern to discuss progress at the end of the first five months of the internship and again close to the end of the experience.

It is also of great importance to develop ways to provide ongoing feedback to interns and give them help in organizing their work. Appendix C is an example of a Progress Monitoring Sheet used to give interns information about their cases and about the success of their interventions. The form is designed to be done in duplicate so the intern has a record of suggestions developed during supervision, and the supervisor has a record of what issues and strategies deserve follow-up attention.

Ethics and Equity Issues

Though rarely the target of litigation, school psychologists have enormously complex ethical dilemmas to face. In addition, supervisors must clearly understand the boundaries that delimit supervisory relationships in terms of exploitation and equity (e.g., appropriate work expectations, gender equity issues, etc.).

Interns. Although the entire practice of psychology is governed by law and ethics, the practice of school psychology has additional demands from laws specific to education and the ethical dilemmas posed by continuous interactions with minor clients. It is clear that intern supervisors should always determine the intern's level of knowledge about current ethical standards and educational laws and regulations as well as associated state mental health laws. Supervisors need to assess this knowledge at the very start of the internship experience, so that interns can be given any needed information immediately.

Beyond knowledge, however, is the ability to apply these principles to daily decision making. Although research supporting the effectiveness of didactic training in ethics is mixed (Welfel, 1992), the efficacy of positive modeling by the supervisor and careful monitoring of the intern's behavior must be

BEST COPY AVAILABLE

accepted as a powerful force influencing interns. Supervisors might find it useful to study Kitchener (1984) and Rest (1984) for information (beyond mere listings of principles) that is useful in developing the ethical decision making and moral development of their interns.

Rest (1984) suggests that an ethical person must have (a) empathy; (b) well-understood rationales for deciding which of the options in a dilemma is morally right or comes closest to one's ideals; (c) ways of selecting among competing values and motivations so that a plan of action can be made; and, finally; (d) the characteristics that allow plans of action to be implemented, such as resoluteness and perseverance.

Kitchener (1984) provides assistance for ethical decision making, especially for deciding among options. She delineates five critical ethical principles for the evaluation of ethical dilemmas in psychology. These principles are autonomy, beneficence, nonmaleficence, justice, and fidelity. Although each of these principles has many applications, a few examples may suggest the richness of Kitchener's (1984) thinking.

Interns should know that a commitment to autonomy underlies our pledge of confidentiality and carefulness in dealing with records. Respecting and promoting others' control of their lives is a key element of establishing therapeutic relationships. Dealing with autonomy concerns with children is quite sensitive. For example, how does the intern handle disclosures from adolescents that implicate family members as abusers but are unlikely to result in the child's removal from the home? How is confidentiality protected when so many professionals have a "need to know" about children?

Nonmaleficence means a promise to "above all, do no harm" and beneficence is associated with psychology as a science and practice dedicated to promoting human welfare. Trainees and supervisors must examine their competencies, the potential negative impact of assessments and interventions, and the client's and client family's civil rights when choosing treatment and assessment options. Unfortunately, there is frequently a price associated with every positive change and interns are often unaware that their interventions or assessments may inadvertently do harm. It is critical to be able to sort through the likely harm and good associated with our professional intrusions into other people's lives.

Justice means being dedicated to fairness. School psychologists are necessarily concerned that each child access an appropriate education. How are situations resolved when one child's access is deleterious to another's? Can a common good be discerned in every situation?

Finally, fidelity refers to honesty in fulfilling commitments and being consistent. Fidelity is owed to children, teachers, school systems, and families, and to personal ethics. Each of these may have differing demands upon the intern — often with compelling rationales.

Too often supervisors and interns may believe that knowing the lists of ethical principles from the National Association of School Psychologists (NASP, 1992) and the American Psychological Association (APA, 1992) may suffice in respect to ethical competencies. It seems clear, however, from the rising numbers of complaints about psychologists that attention to high-level ethical thinking is warranted. In addition, challenges raised by AIDS, teenage health and sexuality decision making, culturally sensitive assessment and intervention efforts, and the changing expectations regarding school psychologists all suggest that ethical training is of critical importance.

Supervisors. Supervisors have many ethical responsibilities toward their interns. Paramount among these may be the management of the supervisory relationship to ensure it is equitable. Although romantic and sexually intimate relationships between female psychology students and their male educators is a well-known fact, nothing is known concerning this issue specifically among school psychology supervisors (Bartell & Rubin, 1990; Pope, 1989). All dual relationships with supervisees are problematic (e.g., intimate friendships, business ventures) but sexual relationships are expressly forbidden. Whatever the experience of the intern or the supervisor at the moment, both should be aware of societal norms that contribute to power differentials between men and women and the great likelihood that sexual relationships will be viewed later by the woman as having been exploitative (Kitchener, 1988). At the very least, the supervisor has failed to model appropriate professional interactions and so has failed to fulfill an important element of his or her contract with the intern.

Sexual and racial harassment are present in most (all?) of our major societal institutions. Supervisors must be alert to even subtle instances of such in their own and their interns' behaviors. Disentangling personal history and social constructions is a very complicated business that may demand outside consultation (e.g., on ethnic/cultural/racial issues) and an ability to be nondefensive. It may be useful for supervisors to consult the *Guidelines for Providers of Services to Ethnic, Linguistic, and Culturally Diverse Populations* (APA, 1990).

Interns' Perspectives on the Process

The interns in the Nebraska Consortium have been asked for the past several years to provide input regarding the quality of their internship experiences. In addition, the second author of this chapter interviewed students who had completed field placements regarding critical incidents in their experience of being supervised. Several themes emerged from these written evaluations and interviews.

Supervisor availability. Interns are sensitive to the accessibility of their supervisors. Even when they perceive the supervisor to be talented and competent, difficulties in contacting a supervisor during a critical period or in arranging for regular supervision result in poor evaluations and a diminished experience. Two hours each week of individual supervision must be given to the interns in addition to other group staffing and educational experiences. Supervisors are permitted to have only two interns and must be organized to have supervisory time available.

Time management. Although all interns expect to work hard, most are unprepared for the intensity of the internship experience. Interns commonly report feeling overwhelmed by the demands on their time and unaware they should take some responsibility for controlling their assignments. They report feeling unwilling to refuse any assignment. This occurs sometimes because they (ambitiously) want to learn everything and sometimes because they fear a negative evaluation if they demur. Very often they lack basic time management and assertiveness skills. These predictable problems sometimes result in interns' engaging in activities that are inappropriate for their role. Not only do they fail to set limits with supervisors, they set no limits with anyone else! Supervisors should be ready to teach these professional management skills to interns.

Exploitation of skills. Some institutions use interns as cheap sources of labor for repetitive or unpopular tasks without a concomitant commitment to training. This attitude is easily discerned by the interns, who resent that their work for the organization is not met with a return of training opportunities. Internships are organized training experiences, not mere on-the-job experiences. This basic fact about internships is often not well understood at the internship site. Careful cooperation between university and internship faculty must be maintained to be sure that everyone stays invested in teaching the interns.

Negative supervisor attitudes. Interns are disillusioned by supervisors who are pessimistic or cynical about professional functioning. Often, under the guise of teaching the intern what the real world is like, supervisors fail to model enthusiasm and optimism in their work. Supervisors may act like victims in their systems rather than instructing interns on how to approach the long and difficult processes of organizational change. Interns may learn more negative information than positive steps to create change.

Personal concerns. The 9-month internship for educational specialist students (1,200 hours) or the 12-month experience for doctoral students (1,500–2,000 hours depending on the state) occurs in the context of family, financial, health, and academic concerns for many interns. The stress on family may be significant because of the intern's time commitments at the site. The internship, even though paid, may represent a serious financial hardship on the intern's family. Many intern programs do not provide health insurance. All of these and a host of other everyday hassles need some attention from supervisors. Although few of such problems, if any, can be solved by a supervisor, all interns seem to appreciate being known in their complexity by their supervisors. Some mutual appreciation of what the training site is offering the intern and what the intern is sacrificing to finish the demanding degree program can help both sides keep ultimate goals in view.

SUMMARY

All supervisors must be well versed both in current guidelines from their professional organizations (APA, 1981, 1992; NASP, 1992, 1994) that speak to basic expectations regarding state-of-the-art training of interns, and in the research supporting supervisory processes (Robiner & Schofield, 1990). Furthermore, they must be cognizant of their own competencies in assuming an educative role with others. These competencies include knowledge, ethics, and personal functioning. The exact sequence of activities offered to interns should be well articulated and responsive to the intern's strengths and weaknesses and academic program expectations. Interns should be offered experiences in the best of professional functioning if the field is to progress. Tired, old, and invalid test batteries should not be imposed on interns, who may arrive at their sites with information new and useful to the supervisors. Enthusiastic, "book-smart" interns should be schooled in the complexities of working in systems that have yet to understand the great potential of psychology.

The vitality of psychology in the schools depends on every supervisor who mentors an intern to high levels of skill, compassion, and the certainty that school psychologists can make a huge contribution to children, families, and the educational enterprise.

ANNOTATED BIBLIOGRAPHY

Bernard, J. M., & Goodyear, R. K. (1992). *Fundamentals of clinical supervisor.* Boston: Allyn and Bacon.
Integrated review of supervision literature from several disciplines addresses professional responsibilities of evaluation, dealing with ethical and legal issues, and developing administrative and organizational skills. Personal and cultural attributes that affect the supervision process are discussed with a special focus on multicultural interactions. The text concludes with transcripts of supervision featuring several eminent psychologists.

National Association of School Psychologists. (1993). *Standards for the credentialing of school psychologists.* Washington, DC: Author.
This revision provides a continuum of supervision including face-to-face supervision, mentoring, and a continuing professional development plan. Two new standards are included: One lists the competencies required in the areas of professional work characteristics, knowledge base, and applied professional practice; the second provides requirements for receiving the NCSP credential.

National Association of School Psychologists. (1994). *Standards for training and field placement programs in school psychology.* Washington, DC: Author.
These standards reflect significant emphasis on knowledge-based and outcome-based training. Students should be prepared for the delivery of comprehensive, intervention-based services. One comprehensive standard for practica is included; practicum experiences are proposed in areas not previously required.

Stoltenberg, C. D., & Delworth, U. (1987). *Supervising counselors and therapists: A developmental approach.* San Francisco: Jossey-Bass.
Developmental levels of trainees are described over eight dimensions: intervention skills, assessment techniques, interpersonal assessment, client conceptualization, individual differences, theoretical orientation, treatment goals and plans, and professional ethics. Progress is traced by using three structures: awareness of self and others, motivation, and autonomy.

Vasquez, M. J. T. (1992). Psychologist as clinical supervisor: Promoting ethical practice. *Professional Psychology: Research and Practice, 23,* 196–202.
Supervisors are responsible for training in three areas: ethical knowledge and behavior, competency, and personal functioning. Vasquez provides a structure for ethical decision making. Supervisor ethics for provision of training and ethical interactions with supervisees are also presented.

APPENDIX A

Self-Assessment of Supervisor Skills and Knowledge

	Needs			Expert	
Teaching Skills					
Identify learning needs	1	2	3	4	5
Write learning goals	1	2	3	4	5
Devise instructional strategies	1	2	3	3	5
Present material didactically	1	2	3	4	5
Present material experientially to explain rationale of intervention	1	2	3	4	5
Evaluate learning	1	2	3	4	5
Comfort in authority role	1	2	3	4	5
Give constructive feedback	1	2	3	4	5
Intervention Skills					
Possess appropriate knowledge bases	1	2	3	4	5
Establish rapport	1	2	3	4	5
Create motivation	1	2	3	4	5
Challenge existing knowledge and attitudes	1	2	3	4	5
Facilitate exploration of skills	1	2	3	4	5
Facilitate exploration of feelings	1	2	3	4	5
Knowledge of interpersonal dynamics	1	2	3	4	5
Model appropriate skills	1	2	3	4	5
Respond with flexibility	1	2	3	4	5
Integrate data into case conceptualization	1	2	3	4	5
Consultation Skills					
Assess problem situation	1	2	3	4	5
Provide alternative interventions or case conceptualizations	1	2	3	4	5
Facilitate brainstorming	1	2	3	4	5
Encourage choices, responsibility	1	2	3	4	5
Function in collegial, collaborative manner	1	2	3	4	5
Manage group/team process	1	2	3	4	5
Commitment to Ethics and Equity					
Knowledge of current ethical standards	1	2	3	4	5
Skills in application of ethics to complex situations	1	2	3	4	5
Skills in enhancing the moral development of interns	1	2	3	4	5
Commitment to creating nonexploitative relationships	1	2	3	4	5
Commitment to equal opportunity	1	2	3	4	5

The following questions may be helpful in framing some of the important issues.

1. In which supervisory role do you have the most experience? Teacher, consultant, counselor? In which do you have the least experience?
2. What is your preferred style?
3. What feedback have you received about your supervision? For example, do you overexplain, are uninvolved, are too verbose, can give examples, are challenging as well as facilitative.
4. What strengths and limitations do you see in your supervision style? How might the strengths be used and the weaknesses by addressed?
5. With what types of learners (interns) are you most comfortable? Consider ethnic/cultural/racial/sexual preference/disability groups when you reflect upon this answer.
6. Can you remember an event of effective supervision you experienced during your training? Do you remember an ineffective incident? Describe the critical dimensions of each.
7. What did you look for in a supervisor? What worked best for you?

APPENDIX B

Psychology Intern Evaluation

Nebraska Internship Consortium in Professional Psychology

Date of Evaluation ______________________________

Intern ______________________________

Training Director ______________________________

Directions: The ratings of the intern should be based upon actual observation and/or reports from staff, clients, families, etc. Circle the number of the scale that best describes the intern's competence. A description of scale points is provided below.

1 – Competence is considered to be in need of further training. Intern seems to lack basic professional maturation in this area. Skill development seems doubtful.

2.– Competence is currently considered below average, but supervision and experience are expected to develop the skill. Close supervision is required.

3 – Competence is at an average level for functioning with moderage supervision.

4 – Competence is assessed to be above average suggesting only a minimal need for supervision.

5 – Competence is very well developed and reflects a capacity for independent functioning with little or no supervision required.

No data – Insufficient information to make a rating at this time.

General Competencies

Rating	**Strengths/Comments**
1. Evaluation — Assessment	
_____ Intellectual	______________________________
_____ Social Emotional	______________________________
_____ Interviewing Skills	______________________________
_____ Behavioral Assessment	______________________________
_____ Personality Assessment	______________________________

Best Practices in Implementing a Staff Development Program

Susan K. Green
School District 5 of Lexington
and Richland Counties, South Carolina

OVERVIEW

Scope of Staff Development

Staff development is a concept that covers a wide variety of efforts in the schools to encourage education professionals to improve job performance. Definitions of staff development by a number of authorities have ranged from the relatively narrow concept of single in-service programs for teaching a particular skill, to comprehensive systems change efforts addressing basic philosophical shifts and redistribution of power in educational institutions. Griffin (1991), for example, suggests that "staff development is a serious and systematic effort to engage a group of professional educators who work together, a staff, in activities designed to increase the power and authority of their shared work" (p. 244).

The staff in staff development can involve educators from superintendents to teachers' aides. In this chapter, staff will refer to educators with direct, daily involvement with children such as teachers and school psychologists. A school psychologist might consult this chapter in a variety of situations — during change efforts such as when a broad school improvement effort is initiated by the district administration, when the school psychologist is asked to develop an in-service on classroom management techniques for teachers, when the school psychologist is asked to help plan a program to improve school management, or when a special education director wants to encourage an outcomes orientation among staff using curriculum-based measurement (CBM) and other progress-monitoring tools. This chapter can also be of use as school psychologists contemplate changes they would like to make toward best practices advocated in this volume. Whether the contemplated change is large or small, similar principles underlie efforts to encourage, instruct, support and evaluate changes in individual or organizational performance.

Justification for Staff Development

The need for staff development in the schools is indisputable. New knowledge about effective instruction, interventions, and content areas increases almost daily, so even the best-trained professional will need frequent updates over the years to stay current in best practices. In addition, the nature of students and the type of problems faced by educators is changing. Teachers are facing an increasing diversity of students with an incredible range of skills from the severely disabled to the gifted. More families are in financial difficulty and their communities are suffering economic recession. Schools are more and more responsible for their students' social as well as academic competence.

In addition, individuals and organizations need to change and learn if they are to succeed in accomplishing their goals or missions. This need is formally recognized by the increasing number of mandates in many states and national organizations (e.g., the NASP certification program) that require continuing education. Effective staff development can refresh and rekindle enthusiasm as new practices are implemented and found to solve problems. Many have argued that schools must foster learning for staff as well as students to be more effective institutions and to model the importance of lifelong learning.

It is also important to highlight that, whether using staff development to attempt broad or narrow changes within a school or a school system, the ultimate justification for any staff development effort is enhancing students' learning. As staff development projects are conceived and carried out, details and logistics can obscure or water down this goal. Keeping in mind the ultimate purpose from the beginning of any discussion of staff development, including this one, is crucial.

Importance of Context in Staff Development

In examining the staff development literature, it is clear that merely providing professionals with information about new knowledge or practices is woefully inadequate for producing behavior change in educators or improved learning in students. Since the early 1980s, authorities on staff development have called attention to the critical influence that context has on the success of change initiatives (Fullan, 1991; Hall & Hord, 1987). For example, because the in-service context is so different from the classroom context, skills needed for transferring learning that take into account these differences have recently been emphasized. Other contextual variables such as degree of administrative support and organizational climate are also seen as important for success. Changes in rewards and norms in the school context must accompany individual learning so that change toward new practices is seen as desirable. It is also contextually important to take into account the needs and experiences of the staff members involved in any staff development effort. Modifying a new program to fit these needs, which vary from school to school, can also help strengthen it. Considerable research and experience across disciplines have demonstrated that context must be taken into account for change to be lasting and successful (e.g., Rogers, 1983).

This chapter will address the issues involved in constructing a successful staff development program, emphasizing those elements of context that are important for producing lasting change. It will also describe basic issues to consider before initiating a staff development program, including taking account of the nature of adult learning, establishing a clear need for staff development, and securing administrative support. Next, the broad steps that many authorities have proposed as a sequence for optimal staff development efforts will be delineated. These include (a) identifying needs and priorities, (b) goal setting, (c) training and feedback, and (d) implementation, evaluation, and maintenance.

BASIC CONSIDERATIONS

Nature of Adult Learning

Before embarking on a staff development program, it is essential that the initiators acquire a background in the nature of adult learning. Moore (1988) has described factors that differentiate adult learning from children's learning that have implications for the design of staff development programs. She indicated that as people get older they are more frequently involved in self-directed learning efforts. That is, they can and do determine their own areas of weakness and take appropriate action to remedy them. Thus, staff developers should design programs that acknowledge and incorporate individuals' capacity for self-direction by encouraging participants to be involved in determining the goals and content of a new program. She also suggested including program components that encourage independent study and, in general, create a collaborative atmosphere. Each of these suggestions is meant to establish a climate of respect for staff members' capacity for independent, self-motivated learning.

A second observation about adult learning with implications for staff development is the prominence of experiential learning for adults. As people get older, they accumulate countless experiences that are often drawn upon as a source of new learning and as a vivid context to which other sources of learning must be connected to be meaningful. Educators' first-hand experience with educating children is a valuable asset in any staff development program. Staff development programs should take advantage of participants' experiences, using them as basic building blocks in developing new skills and incorporating them into exercises or demonstrations. For example, staff members could be asked to use one of the students they have difficulty with in their class as an example to work on throughout an in-service on classroom management techniques. Such efforts can also help keep the new knowledge oriented toward action in the familiar context with an emphasis on problem solving.

On the other side of the coin, however, adult learners often are not willing to question or examine their implicit assumptions and the world view they may have constructed as a result of their sometimes insular learning path. Moore (1988) pointed out the need for staff development programs to encourage critical self-examination of educators' implicit assumptions and values related to their profession.

Perceived Need as a Foundation for Staff Development

Self-perceived needs of staff. Another basic consideration to address before a staff development effort is undertaken is clear evidence of a strongly felt need for it from the perspective of the target staff. A clear picture of these needs and the early incorporation of them whenever possible will help ensure success of a staff development effort by taking advantage of natural interest and motivation. Taking into account these needs does not imply limiting any staff development effort to what the staff wants, which might therefore implicitly endorse the status quo. However, if an effort is undertaken that is more ambitious than currently self-perceived needs would suggest, it is important to consider likely staff concerns and show how they can be addressed by the effort. The school psychologist or other change agent can also work to help identify a need that staff members may not have realized exists. For example, school psychologists who view the assessment for eligibility services that they provide as too narrow may wish to change their role. They could begin emphasizing useful prereferral services, discussing and providing such services to such a point that their success triggers a desire for more formal staff development to create a strong prereferral team and services.

Cultural values. Understanding the cultural values within the school or district targeted for staff development is another element of grounding staff development in the context of self-perceived staff needs. Kantor (1992) pointed out that it is important that staff developers examine their own implicit assumptions and make sure they are not diametrically opposed to those of the staff they are working with. As an example he contrasted "skills" versus "personal growth" approaches to writing instruction, pointing out how difficult it is for an adherent of one approach to work with advocates of the other. Kantor implied that a skills or a personal growth writing instruction model can pervade the way a school is organized, making a new model impossible to adapt. Even if staff are attracted to new approaches, they may sense that those approaches will not work in their present school context. Differences in unspoken beliefs, assumptions, and values can be uncovered and addressed if careful assessment of a staff's needs is undertaken before a staff development effort begins.

Organizational climate. Assessing the school's organizational climate — the effectiveness of its formal and informal procedures, communication processes, and norms — is another element to consider when examining the need for staff development. Research has shown that students' achievement is higher and innovations are more effective in schools with a more positive climate, as measured by good problem-solving and renewal capabilities, opportunities for teachers to learn and collaborate, and workplace commitment (Rosenholtz, 1989). It is useful for the staff developer to assess the organizational climate to see if the school or district has structures already in place to solve problems, make decisions, deal with conflict, and clarify communication. If a poor organizational climate exists, efforts to improve it can be built into the staff development project as they are relevant to the content of training. Organizational development, which is a conceptual framework for developing strategies to improve the functioning of organizations, has been used in schools and other organizations for many years (Schmuck, 1990). Schmuck and Runkel (1994) have reported that a recent trend promoted by the National Council on Staff Development is to integrate organizational development activities that improve climate with professional development related to acquiring new skills or changing educational procedures. For example, if a staff wants to develop a schoolwide discipline program, the staff developer can include exercises and information on improving decision making related to discipline and on effective conflict resolution. If a staff wished to institute a weekly prereferral intervention team meeting, a staff developer could include components on running effective meetings and on techniques for successful role clarification.

Schmuck and Runkel (1994) have suggested a number of ways to assess organizational climate that are based on extensive research in organizational development. Informal observations can illuminate many aspects of the communication process, such as whether unpleasant feelings are shared only privately rather than at general staff meetings, whether trivial issues are discussed at length while important ones are ignored, and whether conflicts are appropriately resolved. More formalized methods such as systematic interviews and questionnaires can also be used to develop an overall picture of communication and organizational climate at a school. Schmuck and Runkel (1994) have suggested that school organizations that are most adaptable in constructively managing change exhibit four metaskills: *diagnosis*, which involves frequent formal and informal monitoring of organizational functioning; *gathering information and resources*, which involves searching out additional resources when information is not available to solve current problems; *mobilizing synergistic action*, which involves having staff members coordinate their actions in new patterns rather than initiating changes individually; and *monitoring the first three metaskills*, which involves frequent overall assessment of whether the staff is using the first three skills to move in the direction they would like to go.

Administrative Support as a Foundation for Staff Development

Another important preliminary consideration is determining the extent of administrative support for any staff development effort. The need for a multilevel orientation to staff development is essential, according to many staff development experts (e.g., Pink & Hyde, 1992). Pink and Hyde, in analyzing a group of staff development case studies, recommended that representatives at the levels of principal and central office staff — as well as targets of staff development efforts who will be working directly with students — be involved at the outset of every staff development effort. They provide the support necessary to sustain a change effort, such as smoothing logistical problems and providing incentives. Also, if principals and other administrators are not involved, it communicates that the staff development effort has a low priority, so staff are unlikely to view the changes being sought as important. The important role of supervisors such as principals is dramatically illustrated in a study of implementation of problem-solving consultation conducted by Reschly and Flugum (1993). They found that if staff development participants had supervisors who expected them to complete cases by the new methods and if these expectations were incorporated into their annual personnel evaluations, 84% of the participants incorporated the new procedures. If there was no such support and operationalized expectation, only 13% incorporated new procedures. These findings highlight the need for administrative support clearly specified in concrete ways. The best time to secure that support is to build it in from the inception of any new change effort.

Attending to perceived need on the part of the staff and securing strong administrative support are both crucial to successful staff development. Sometimes such a broad base of support is not possible and a more informal person-by-person approach is the only alternative. However, staff developers agree that the changes needed in norms and incentive patterns to make change desirable entail a supportive organization as well as enhanced individual skills. A great deal of research on school change suggests that successful change requires both "top-down" and "bottom-up" efforts and support (e.g., Bullard & Taylor, 1993), and this dual approach should be pursued whenever possible.

Time as a Basic Consideration

Change takes time, usually more time than people estimate. Pink and Hyde (1992) concluded from their analysis of staff development case studies that providing sufficient time for planning and implementing staff development efforts is central to success. They have suggested that for serious change, people should adjust their estimates from months to years. Developing a clear sense among all involved of exactly what should change and how it can best be accomplished is necessary — what Fullan (1991) termed "shared meaning." Collaboration, reflection, practice, and preparation all contribute to the development of shared meaning and occur only gradually over time. For changes to be long-lasting and successful, ideas and practices from outside must be incorporated into and adapted to the context in which the staff work and the practices the staff already have.

BEST PRACTICES IN IMPLEMENTING A STAFF DEVELOPMENT PROGRAM

This section will be organized according to broad steps many authorities have described as a logical sequence for staff development efforts. The principles to consider as well as the general activities involved will be discussed within each of these steps. Table 1 presents an overview of the steps, the issues involved at each step, and sample activities.

Step 1: Identification of Needs and Priorities

Identifying the needs and priorities for a new staff development effort must be handled with care but also with efficiency. A staff developer must balance the needs of the staff, the administration, and other interested groups, whose perspectives are very different and, therefore, whose ideas about what is needed may conflict. Involving staff members is essential in this process because it helps them "own" the staff development effort, and it gives them an appreciation for the kinds of conflicting ideas that must be melded into one program that has as its ultimate goal enhancing students' learning. Self-perceived needs of the staff, organizational climate and philosophy, and administrative support are issues that must be explored thoroughly in the identification of needs and priorities step.

Schmuck and Runkel (1994) have described a systematic problem-solving technique that can be used as part of the process of identifying needs and priorities for a staff development effort. They have suggested that a problem exists when there is a discrepancy between the present circumstances or situation and the ideal situation the staff would like to achieve. The problem is solved — or, in this case, the focus of the staff development effort is clarified — when a path is chosen between the present situation and the target.

The following are the steps relevant to the process of identifying needs and priorities.

Come to agreement on the problem. Staff members come to consensus on the nature of the present situation (e.g., that discipline is inconsistent at their school, that rates of student infraction of discipline rules are too high, and that staff members feel the need for additional training in classroom and playground management). They must also agree on feasible targets (e.g., to increase the management skills of the staff, to implement a schoolwide discipline program, and to increase students' rule following). Systematic gathering of data is important at this step. To assist in this process, devising a questionnaire that asks the staff to rate their own degree of competency and their degree of interest in a list of skills, for example, is one technique that could systematically provide input from many people (Frase, 1992). Oldroyd and Hall (1991) also have suggested staff development interviews, which can be more flexible and personalized, a consideration that is especially important in more comprehensive staff development efforts. At the school level, holding group discussions can provide illuminating information. In summarizing both qualitative and quantitative data, Oldroyd and Hall have cautioned that the criteria for analyzing information and establishing priorities should be developed and agreed upon by everyone beforehand so that the outcome will be seen as fair.

Generate alternative paths. Staff members come up with alternative plans for moving from the present situation to the target. Brainstorming and using outside resources can be especially helpful at this step. For example, staff members may suggest several types of discipline techniques they would like

TABLE 1
Steps, Issues, and Activities in a Staff Development Program

Steps	Issues	Activities
1. Identify needs and priorities	Staff self-perceived needs Organizational climate Organizational philosophy Administrative support	Gather and summarize data (e.g., surveys, interviews, staff meetings)
2. Goal setting	Specific goals Staff participation in goal setting Frequent feedback	Quantify goals Specify measurement Specify time frame
3. Training and practice	Executive control Shared meaning	Present effective techniques Present specific information Incorporate practice and feedback Build in choice and control Incorporate stages of concern
4. Implementation, evaluation, and maintenance	Formative and summative evaluation Nonjudgmental follow-up Change as a process not an event	Schedule group meetings that incorporate regular feedback Express administrative support Celebrate

to study in small groups; alternatively they may suggest attending professional conferences and workshops. They might also suggest examining schoolwide discipline plans from other schools in their state.

List helping and hindering forces. Staff members describe forces that will foster or interfere with efforts to reach the target. For example, helping forces could include technical assistance from faculty at a local university, administrative support, or skills some members of the staff already have. Hindering forces could include lack of skill on the part of staff members, a vacillating principal, or a poor organizational climate.

Choose action steps. Staff members choose helping forces to mobilize and they work on eliminating or reducing hindering forces. For example, the staff could decide to hold a series of in-services on classroom management that focuses on the skills the group feels they need most. They could also decide to stage a series of meetings with the principal to clarify discipline policy and to have an organizational development expert serve as facilitator.

The examples involving school discipline described above illustrate the process of identifying needs and priorities from within a school. This process can also be undertaken by an outside staff developer. As part of the process, it is crucial for the staff developer, whether an insider or an outsider, to have a good picture of the environment in which the staff development program will take place. Awareness of the organizational climate and the philosophies of the staff, knowledge of who the opinion leaders (or influential people) are among the staff, and a clear understanding of the administration and its priorities as they may affect the topic of the staff development program can be keys to ensuring success.

Step 2: Goal Setting

After forming a clear picture of the needs to be addressed in the staff development program, setting concrete goals that provide focus is essential. Effective goal setting at the level of the district, the school, and especially the individual is the step that ensures that staff members will focus on outcomes related to tangible changes in behavior rather than viewing in-services or other staff development efforts as largely a more vague broadening of horizons. Goals should be developed in the context of district priorities, and they should be established with a clear connection to daily work. For teachers, goals can be developed relating to their own actions in the classroom (e.g., incorporating a review of classroom rules in morning opening exercises each day; monitoring at least three students' reading progress using CBM or other means). Schoolwide goals can also build on and interweave with individual goals (e.g., reduce office referrals for rule breaking by 50% by June; increase the number of third graders reading over 100 words per minute by 20% by December). To be effective, these goals must later be used for evaluation to determine whether the program has been successful. They can also be incorporated into performance evaluations and other naturally occurring assessments in the school context.

Principles of effective goal setting. Much research on the effectiveness of goal setting has been conducted by industrial/organizational psychologists.

Research on organizations has shown unequivocally that specific goals improve performance on the job. Locke and Latham (1984) have summarized this research by highlighting the most effective principles involved in successful goal setting. First, having a *specific goal* provides a clear objective to pursue that is not available with vague exhortations to "Do your best." Second, *participation* in goal setting by the staff greatly increases acceptance of the goal. If people participate in setting a goal, they are more likely to accept the goal as legitimate than if it is assigned by their supervisor. People are more committed to choices in which they have a say. Third, *feedback* on progress toward goals improves performance because feedback provides a benchmark for judging behavior.

Procedures for successful goal setting. Locke and Latham (1984) have recommended that goal setting procedures involve (a) choosing a difficult but attainable goal and quantifying it, (b) specifying how performance will be measured, and (c) specifying the time span involved. From extensive research, they have concluded that "goals facilitate performance in four ways: they direct attention and action, they mobilize energy, they increase persistence, and they motivate the development of appropriate task strategies" (p. 26).

Use of specific goals helps a staff come up with measurable and verifiable actions and outcomes that should flow from the staff development program. Spending time on goals up front makes implementation, evaluation, and maintenance of change much easier because criteria for success have already been established. As people gradually move toward their goals their progress can be monitored, and the gap between the goal and current performance can be used for continued training and improvement. Also, clear expectations can reduce anxiety and misunderstanding among staff who are learning new techniques and behaviors.

Step 3: Training and Feedback

Several principles have proven effective in the design of training for successful staff development. Perhaps the most important of these is the need to ensure that the training transfers from the training context back to the everyday school context. To elaborate this principle, Joyce and Showers (1983) have discussed the important concept of "executive control," which they define as

> understanding the purpose and rationale of the skill and knowing how to adapt it to students, apply it to subject matter, modify or create instructional materials attendant to its use, organize students to use it, and blend it with other instructional approaches to develop a smooth and powerful whole. (p. 8)

Joyce and Showers maintain that in many jobs (the military, the factory assembly line) standard operating procedures are developed so that workers exercise their own judgment as little as possible. In education professions, however, people are called upon to use their own judgment frequently and there are few standard operating procedures; thus "executive" skills are required. As a result, any staff development training cannot simply enumerate a set of skills or standard operating procedures. Transferring skills in which judgment and adaptation must be relied upon must also be explicitly trained.

Executive control is developed by first working on a skill, then practicing it in the workplace while feedback and coaching are provided. These kinds of additional activities allow staff members to develop the conceptual framework for integrating new skills into current practice, to alter or eliminate other practices that interfere with them, and to exercise judgment effectively. For example, in the early stages of developing a schoolwide discipline program, after deciding what behaviors represent following school rules, teachers might collaborate in pairs at recess, taking turns at working with children (e.g., providing behavior-specific praise, using agreed-on correction procedures) and observing (e.g., providing feedback on the consistency and fairness of the other teacher's actions).

In a comprehensive review of the literature on staff development, Showers, Joyce, and Bennett (1987) concluded that the most effective staff development efforts did indeed involve not only presentation of information, but also demonstrations and opportunities for practice and feedback. They suggested that the practice and feedback components give staff members more of a chance to develop the judgment skills that permit them to use new methods appropriately and adapt them to their needs. The concept of executive control echoes the principle of shared meaning. Both highlight the complexity involved in the gradual process of incorporating new ideas and practices into a preexisting system.

Within the broad framework of developing executive control as a goal, several principles are useful in designing staff development presentations. It is important to note that the major responsibility for designing and conducting such presentations should rest with the presenter, because research has shown that training is more effective when presenters rather than participants are in charge.

Present effective techniques. Given the high investment of time and resources in staff development training, it is essential that any new techniques the staff learns have been proven effective through appropriate research. Education has been prey to many fads, and it is important that new practices be grounded in careful research showing positive effects on students' learning. In addition, Guskey (1985) and others have pointed out that changes in educators' attitudes toward specific new practices occur only after they have seen them improve their own students' outcomes. Thus, for comprehensive attitude change to take place, the new strategies being learned must work. Guskey's model also suggests that spending too much time on getting commitment from staff before the staff development effort is under way can be fruitless. Comprehensive commitment to any particular new methods comes only after the staff sees that they work in their own school. Guskey's perspective particularly emphasizes the need for teaching only well-documented, effective techniques in staff development training.

Present well-defined, concrete, and specific information. The staff development literature suggests that the more explicit and concrete the material presented, the more clearly it is understood and assimilated by staff (Duttweiler, 1989; Hinson, Caldwell, & Landrum, 1989). Vague concepts end up even vaguer as they go through the complex process of interpersonal communication that is intended to foster shared meaning. The first elements of every staff development training should involve demonstration and presentation of information. Demonstration can include descriptive case examples, videotapes, and modeling of sample problems and their solutions. For example, when teaching educators to make graphs for monitoring students' reading progress over time, it is important to explicitly describe the rationale, to lay out the measurement system, to explain the scale used for labeling the graph, and to walk through several examples. One should not automatically assume that everyone is familiar with the conventions of graphing. Similarly, when designing and implementing a schoolwide discipline program, it is important to provide concrete steps for teaching the rules to children by demonstrating the use of examples of appropriate and of inappropriate behaviors. Detailed presentations of information and demonstrations are a necessary building block for later steps in staff development training. Before techniques and strategies can be used effectively, the foundations and actual procedures involved must be unambiguously established.

In this regard it is helpful to provide written materials and worksheets to accompany any presentation. It can also be helpful to solicit oral and written feedback from staff development participants. If participants write down their questions, concerns, and reactions to presentations, in regular "reaction papers," the staff developer can get a clearer picture of how they are thinking about the material and can plan future sessions to address appropriate concerns and reexplain difficult concepts.

Provide opportunities for practice and feedback. In a comprehensive review of the effectiveness of in-service education, Wade (1984) concluded that four types of in-service instruction are significantly more effective than others: observation of actual classroom practices, microteaching, video/audio feedback, and practice. (Instructional methods that appeared to be much less effective included discussion, lecture, games/simulations, and guided field trips, which perhaps have the potential to stray more easily from the goals of the training to something more rambling and less focused.) The first of these — observation — is important for clear, concrete presentation of new techniques, as discussed in the previous section. The other three techniques identified by Wade provide structured, task-oriented opportunities for educators to experiment with new practices and reflect on them in their typical context, prerequisites for developing executive control. An example of a somewhat casual use of such opportunities is trying out techniques in the classroom or other setting and informally noting the effects on students. Microteaching, in contrast, involves teachers preparing and teaching a short lesson (5–20 min.) to a small group of students, which is taped to provide feedback. Structured peer critiquing in which constructive feedback is provided after a staff member is observed while trying out new strategies in the typical context also can be helpful in integrating new techniques into everyday practices.

Other authors have recommended coaching (e.g., Joyce & Showers, 1982), in which a more experienced colleague assists a less experienced colleague in learning new practices, providing companionship, feedback, and analysis. Such coaching must have structured and goal-oriented sessions, a mutually respectful relationship, and built-in efforts to foster the independence of the trainee. In any case, most authors agree that practice and feedback arranged through opportunities for structured interaction are crucial for effective training that promotes executive control.

Research has also shown that one-shot in-services are rarely as effective as ongoing staff development efforts. The need for practice and feedback before new techniques can be incorporated into a staff's everyday practice explains why one-session efforts can fail. Building on experience and encouraging cumulative learning over time enhances stronger commitment and deeper learning of new skills.

Build in staff choice and control. Because adult learners have the capacity to be self-directed in pursuing their own learning needs, some element of choice and control needs to be built into staff development training efforts to convey respect and to take into account expressed interests. Once the overall goals of the staff development effort are chosen and agreed upon, staff participation comes into play in the process of practice and feedback. For example, in staff development training on classroom management, teachers could choose which students in their rooms or periods of the day to focus on while in practice and feedback phases. In an effort to implement cooperative learning, teachers could choose which subject area and how diverse a group they will work with in implementing a new group activity. These types of choice allow staff members to set their own level of challenge and to decide where current practice can best be modified.

In addition, staff choice and control can be incorporated into broader types of change in a district. For example, in developing a new districtwide special education effort to monitor students' progress, teachers could choose monitoring material and the form the graphs will take. Getting staff feedback on new procedures can help improve the procedures and adapt them to the needs of the school or district as well as help make the staff members feel included. The perception of choice and control has been shown in extensive psychological research to be an important determinant of a sense of well-being (e.g., Yates & Aronson, 1983). The types of choice and control, however, need not always be major or dramatic. For example, energy conservation researchers have found that consumers are much more willing to install automatic day–night thermostats if they are designed to allow people to override the system temporarily, even if the override system is never actually used.

Incorporate staff stages of concern. Hall and Hord (1987) have developed the Concerns-Based Adoption Model, a conceptual model describing the process educators go through as they experience change. Their model is based on the assumption that the point of view of the participants in the change process is crucial to success, and it is up to staff developers to systematically probe and understand these concerns. One element of their model, the stages of concern, is particularly helpful in designing staff development training.

Hall and Hord have suggested that change is a personal experience for each individual involved, and people go through predictable developmental stages as they respond to it. At each stage different perceptions, motivations, and feelings predominate, so it is important for staff developers to address the appropriate concerns and adjust their presentations to them. The first stage of awareness involves *self concerns.* The early level of this stage involves general awareness and interest in learning about new practices. Concerns at this level can also be defensive — doubts about one's adequacy to handle new techniques, potential conflicts generated, and status implications of the change. *Task concerns,* the next level of the model, involves focusing on managing new procedures, such as scheduling and logistics, efficiently. At the last level, *impact concerns,* staff members become concerned primarily with cooperating with others to implement the change and impacting students in the most effective way.

To learn about the concerns participants have and to classify them into stages, staff developers can analyze written answers to open-ended questions (e.g., When you think about this change, what are your concerns? How does this change affect you?), or engage in "one-legged conferences." One-legged conferences involve brief, informal checks (e.g., passing in the hall or lunchroom) on how the new program is going that provide an opportunity to get a sense of the staff member's concerns. The questioner then follows up by doing something to respond to the concerns expressed. One-legged conferences take advantage of typical casual encounters that staff developers often have with staff. This kind of work is especially important when the staff development effort is starting to focus on practice and feedback elements. For example, if a teacher mentions in passing that he or she is having difficulty helping students understand the rule "Respect others," the consultant working on a schoolwide discipline plan with the staff could jot down a few suggestions that had been effective for other teachers and put them in the teacher's mailbox. Hall and Hord (1987) have reported that success or failure of staff development programs can hinge on the use of one-legged conferences to encourage and support the staff who are initiating the new projects. Such conferences can be especially helpful for providing quick feedback related to the change, for correcting erroneous impressions, or for adding a crucial piece of information that could have been missed in the first exposure to the new material.

Perhaps the most crucial stage for this kind of personalized interaction is the self concerns stage, when individuals may be feeling uncertain or inadequate about the change and have the potential to respond defensively and reject the change to maintain self-esteem. In the competition between familiar and new patterns, the familiar usually wins out unless the incentives to embrace the new are potent. Frequent interpersonal contact can help keep the incentives salient. Also, when encouraging people to adopt new behaviors, personal contact is more effective than more impersonal means because it can target the concerns that have surfaced at the moment. Change is always accompanied by ambiguity, and it is important to keep track of people's concerns so that the uncertainty doesn't mushroom into elaboration of worst-case scenarios and rejection of the new ideas.

Step 4: Implementation, Evaluation, and Maintenance

Implementation. When new procedures are ready to be implemented after early rounds of training, practice, and feedback, mechanisms for continued interaction and feedback must be in place. A nonthreatening, nonjudgmental stance is essential for such support to be effective. Continuation of one-legged conferences can be helpful, but more formalized procedures may also be called for. Regular small-group meetings in which problems are discussed and solved or a mentor system in which more experienced colleagues meet regularly with newer staff members to work on implementation issues are two possibilities. Incorporated in such a process should be regular feedback to staff members on the individual and group goals chosen at the beginning of the staff development effort. For example, once a schoolwide discipline plan has been implemented, teachers should continue meeting regularly to review patterns in data collected on playground referrals to make sure they are moving toward target rates. They can also review teaching and correction procedures that prove to be problematic, and they can deal with other issues that arise in day-to-day practice. A key element of such efforts is to encourage an atmosphere of collaborative problem solving at the school to reduce staff isolation.

As new practices are implemented, it is also important for administrators to demonstrate support for the new activities. Such support can be shown by providing participating staff members access to resources such as additional materials or release time for planning. Administrators can also offer encouragement and recognition by keeping abreast of the changes, showing an interest in how things are going, and providing incentives for goal attainment.

Evaluation. With implementation comes the need for evaluation. An obvious source of information is *summative evaluation:* examining whether the goals defined when the project was first developed have been met. For example, determining whether classroom and schoolwide discipline referrals have decreased would be useful at a school where the staff development effort focused on teaching children schoolwide rules. Examining whether students are reading more fluently would be useful at a school where the staff development effort focused on implementing a new progress-monitoring system.

In addition, *formative* evaluation also is needed to address how and to what degree new practices are being implemented and adapted by the staff and whether progress toward ultimate goals is being made. Direct observation of the extent to which new practices are in place can be helpful. For example, observing in the classroom how often teachers discussed, modeled, or taught classroom rules or examining graphs of students' academic data to determine whether progress was being correctly monitored would provide information on the extent of implementation of new procedures in the examples above. To get the most accurate information, such data should be gathered directly through observation rather than second-hand through questionnaires.

Gathering formative evaluation data is important for diagnosing weak spots that need improving. It also provides reinforcement to participants who can profit from formative feedback showing they are making progress toward their goals. It can also be used to show that the new procedures were, in fact, implemented with fidelity and that any outcomes can truly be attributed to the staff development effort rather than to extraneous variables.

Maintenance. Many staff development writers cite Hall and Hord's (1987) basic assertion that change is a process not an event. Implementation of a staff development effort is not an event that abruptly grinds to a halt after objectives have been met. The staff development effort that has been well integrated into the school's, or the school district's, mission should move easily to a maintenance phase in which new practices are integrated into the staff's daily behavior and monitoring continues. This phase involves continuing support for staff. For example, Killion and Kaylor (1991) have described follow-up techniques that involve regular group meetings focused on problem solving, feedback, and assistance for implementers. These kinds of groups can also provide a mechanism for monitoring or enhancing organizational climate. They can help people feel they are an important part of the project's success and can promote job satisfaction. Continuing leadership and enthusiasm by administrators is also important. Regular supervision and evaluation of staff incorporates goals developed as part of the staff development effort. In addition, particular attention to the continuing impact on the students' learning is important.

Finally, at the maintenance phase (and at other phases as well) it is important for the staff to celebrate its successes. Recognizing people for their accomplishments with, for example, a round of applause at staff meetings, a letter from the principal, an announcement in the newspaper or school newsletter, or special certificates, can go a long way toward validating people and their efforts to improve the schools they work in. It is important to recognize and honor staff members who go the extra mile and take on the challenges that staff development can bring into the already complex world of the school.

SUMMARY

Staff development covers a wide variety of efforts in the schools to encourage education professionals to improve job performance. The ultimate justification for any staff development effort is to enhance the students' learning. Since the early 1980s, educational leaders have come to understand that the overall context in which staff development occurs influences the success of any effort. For example, it is crucial to establish a clear need for staff development on the part of the staff involved, and it is essential to secure strong administrative support for staff development efforts.

The preliminary steps in implementing a staff development effort include (a) Identifying needs and

priorities of the staff, and (b) Setting goals for feedback and evaluation. Designing and implementing the training is the next step. A major consideration when designing staff development training is the need to address the transfer of new knowledge from the training back to the everyday context. To this end, staff development experts have suggested that specific, effective techniques be presented in training with plenty of structured and informal opportunities for practice and feedback. It is also important to build in choice and control for the staff during training activities and to tailor training to the needs and concerns that staff express at different stages of the learning process. The final (but ongoing) step in staff development efforts combines implementation, evaluation, and maintenance activities. Ongoing formative and summative evaluation is encouraged at this step as well as continued administrative and collaborative peer support. As the new staff development program is maintained, an emphasis on celebration and recognition of accomplishments is helpful.

ANNOTATED BIBLIOGRAPHY

Brandt, R. S. (1989). *Coaching and staff development*. Alexandria, VA: Association for Supervision and Curriculum Development.
This book contains readings from the journal Educational Leadership that pertain to staff development. Articles are divided into sections on building a culture for professional growth, research on teaching, research on staff development, collegiality, and coaching.

Caldwell, S. J. (1989). *Staff development: A handbook of effective practices*. Oxford, OH: National Staff Development Council.
This book provides discussions of basic issues in staff development organized around themes of process, content, and context. Chapters on process address how training is designed and how enthusiasm is sustained. Chapters on content address use of research methods and content. Chapters on context discuss the interplay of district, school, and individual needs.

The *Journal of Staff Development*, which appears quarterly, provides many interesting, timely articles on a wide variety of aspects of staff development. Two recent articles provided general themes for effective staff development programs (see Duttweiler, 1989, and Hinson et al. 1989 in the reference section). The journal also provides descriptions of successful staff development programs (e.g., on multicultural education or instructional changes), think pieces on general issues (e.g., the

balance between process and content; influencing decision makers), and articles on specific elements of staff development (e.g., follow-up activities, in-service presentations).

Locke, E., & Latham, G. (1984). *Goal setting: A motivational technique that works!* Englewood Cliffs, NJ: Prentice-Hall.
This book summarizes the goal-setting literature in organizational psychology and lays out the most effective methods for goal setting. The chapters on how to set goals, how to obtain commitment to goals, and how to implement goal setting are particularly helpful for implementing goal-setting techniques as part of a staff development effort.

Schmuck, R. A., & Runkel, P. J. (1994). *The handbook of organizational development in schools* (3rd ed.). Palo Alto, CA: Mayfield.
This thorough handbook provides a guide to using organizational development techniques to improve communication and help schools solve interpersonal problems. Step-by-step techniques are provided with sample exercises and interesting examples of these techniques in action in schools. Helpful chapters on improving meetings, working with conflict, and clarifying communication can assist in improving organizational climate.

Best Practices in Applied Reseach

Timothy Z. Keith
Alfred University

Why bother with a chapter on research? Conventional wisdom is that school psychologists are not interested in conducting research and that many are antagonistic toward research. Yet my experiences teaching and conducting workshops on research and writing about research for the practitioner-oriented journal, *School Psychology Review*, lead me to believe that the conventional wisdom may be conventional but it is not wise. Many school psychologists have expressed an interest in conducting research in applied settings and many more want to do a better job of incorporating others' research into their daily practice. Both of these are appropriate research roles for school psychologists.

For the purpose of this chapter, research is defined as activities designed to produce new scientific knowledge or to use that knowledge to improve school psychological practice. Three hierarchical research roles for school psychology are indicated:

1. All school psychologists should strive to be competent *consumers* of research. The types of people we serve, our methods and our instruments, and our roles are constantly changing. At the same time, there are always plenty of bandwagons tempting us to hop aboard. The best way to stay abreast of current developments while avoiding bandwagons is the careful reading of research. Research tells us which good ideas really *do* work.

2. There is also a need for a smaller number of school psychologists to act as *distributors* (or synthesizers or disseminators) of research. They may read research relevant to a topic of interest and summarize and draw conclusions from it for other interested groups, such as other psychologists or a Board of Education.

3. Some school psychologists are interested in performing the role normally considered research: *conducting* research of interest to themselves, their colleagues, or their employers.

The three roles are hierarchical because one needs to be an effective consumer of research to summarize and distribute it effectively, and one needs to be able to summarize research to be an effective conductor of research.

As an example, consider three school psychologists interested in the effectiveness of study-skills instruction. John, a research consumer, is interested in study-skills instruction as an educational intervention for a low-achieving child. He reads research to find out if study-skills instruction is generally effective in improving achievement, which methods of instruction are available, and whether some methods are generally more effective than others, particularly with children similar to the one John is working with. Elaine, a research distributor, is asked by her superintendent to investigate whether it would be worthwhile to teach study skills to incoming high school students and, if so, which approach would be most effective. Finally, Carolyn conducts research comparing the achievement of students in her district who were taught study skills to those who were not.

BASIC CONSIDERATIONS

The Consumer of Research

Although social science research is often contradictory, it is also the one way we have of putting aside our hopes and prejudices and testing whether an intervention works or not. To serve children well, psychological practice needs to be consistent with research findings. Yet research is contradictory, and much research is of poor quality and limited applicability. School psychologists thus need to evaluate the research they read in order to separate the good from the bad.

To evaluate research, one asks two essential questions. Did the research demonstrate anything, and is it applicable to my situation? The training needed to become a competent consumer of research is not extensive and is probably included in most specialist-level school psychology programs. Basic statistics, research, and measurement courses, which focus on a *conceptual* at least as much as a numerical understanding, are needed. Unfortunately, many such courses continue to be taught as if most students were going to be conducting research rather than reading and evaluating it: More attention is needed toward the *evaluation* and use of others' research. Single-case research methods also need more coverage; this is one research method that practitioners need to use, but its coverage is spotty. The primary resource needed by consumers of research is access to relevant journals.

The Distributor of Research

Although all school psychologists should strive to incorporate research results into their practice, all do not need to integrate and distribute research to others nor conduct research. Whether one becomes a distributor or conductor of research should be a matter of choice and job description.

Research distributors first need to be good research consumers and they additionally need experience sifting through and integrating research findings which may be rather diverse and inconsistent. Their formal training should also include at least basic courses in research, statistics, and measurement and, at least as important, guided experience in integrating and summarizing research. All doctoral and many specialist-level psychologists should have this level of training and at least some experience, at minimum, when writing a thesis or dissertation.

Research distributors need access to a wider range of journals and other sources of research: conferences at which research is presented, the ERIC Document Reproduction Service, and *Psychological Abstracts*. Electronic data bases such as ERIC and PsycLit — to be discussed in more detail later in this chapter — can enhance greatly the effectiveness of research distributors by providing the ability to search a broad range of journals. Access to a university library is also extremely useful.

The Conductor of Research

It is well known that not all school psychologists are interested in conducting research, but this role should — and often is — available to psychologists with the appropriate interest and training. Again, these roles are seen as hierarchical; one needs to be a competent distributor of research in order to be a good conductor of research, because the conclusions drawn from previous research should guide the research conductor's efforts.

The formal training of those who plan to conduct research needs to be more extensive and should include a series of research methods and statistics courses. Nevertheless, most doctoral level and some specialist level psychologists have completed such coursework, to interest and experience tend to be more limiting. Probably the best training for this role is to assist someone else in several research projects or to conduct several research projects under supervision (in addition to a thesis or dissertation). A graduate research assistantship or some sort of research apprenticeship can be extremely valuable.

The conductor of research needs access to the same resources as the distributor of research: research publications and a good library. In addition, most psychologists who conduct research need access to a computer with a good statistical analysis program.

BEST PRACTICES

Consumers

Reading and evaluating research. Consumers of research read and evaluate research as a means of improving their practice. To perform this role one must, of course, have access to relevant research. Consumers must also be able to evaluate the research they read. Much research in the social sciences is contradictory, and an effort to find the research answer to a question of practice can be quite frustrating. I do not believe this inconsistency means that research cannot inform practice. It does mean however, that *evaluation* of the research is necessary.

Journals, the primary source of research, accept only a fraction of the articles submitted for publication, thus supposedly ensuring that the research they do publish is of high enough quality to deserve our trust. Nevertheless, much research, even that published in good journals, is not good research:

- Research problems are poorly conceived or are trivial.
- Samples are small and poorly selected.
- Inappropriate statistics are used or mistakes are made in calculating and reporting statistics.
- Research designs are weak and do not rule out plausible alternative hypotheses.
- Designs do not fit the purpose of the research or do not test the hypotheses the researcher wants to test.

Even when research is well-conceived and conducted, there are problems of interpretation. Most researchers have been guilty of overblown conclusions that extend well beyond what might reasonably be concluded by the results, but more subtle problems are common as well. It is not unusual, for example, for a discussion to address a different issue than that addressed by the research! This problem is common when a mismatch occurs between the intended purpose of the research and the research as actually conducted. For all of these reasons, much research is of poor quality, and consumers of research need to evaluate carefully the research they do read.

Fortunately, one does not have to be a statistician to evaluate research. Instead, what is needed is a *conceptual* understanding of research methods and what those methods can tell you. What is the purpose of a representative sample? Of random assignment to groups? When is research experimental and when is it nonexperimental? What threats to validity does a multiple-baseline design control? What does significance mean? What does analysis of variance, or multiple regression, or factor analysis tell us? Being able to answer these conceptual questions will help one evaluate research much more so than being able to calculate t-tests by hand. One also needs to read research articles carefully — even skeptically.

Research evaluation focuses on a number of different aspects of the research, but there are three very important considerations. First, are the internal features of the research conducted well enough so that the research consumer can have confidence in the results? This consideration is generally referred to as the internal validity of the research (Campbell & Stanley, 1963) but may also be thought of as the "power" of the research design (Keith, 1988). In other words, is the research design powerful enough so that we can be confident that it was the *treatment, and not something else*, that caused the resulting change in behavior?

Second, how generalizable or applicable are the results? This consideration — external validity — focuses primarily on the subjects used in research and the treatments. Are the people used in the research study similar to those one might encounter during normal practice? Are the treatments used similar to those that might be used in applied settings, or have they been modified drastically to fulfill the requirements of the experiment? There is often a trade-off in these two aspects of research. For example, a school-based study in which various classes were assigned differing amounts of homework would likely be less powerful (more threats to internal validity) than a lab-based experiment in which college freshmen were assigned randomly to groups and given different amounts of time to study nonsense words. On the other hand, many would probably feel more comfortable generalizing the results of the first study to a middle school student who does not complete his homework. The second study is more powerful but less generalizable.

Third, is the article written well enough so that readers can understand what was done and the implications of the results? It does not matter how technically sophisticated research is if the writing is unclear and confusing.

Although skepticism is necessary in evaluating research, it should not be carried to an extreme. Be warned: *No research is perfect!* Conducting research consists, in large part, of making decisions and compromises, and there are weaknesses in any piece of research. When evaluating research, one needs to weigh its strengths and weaknesses and decide whether the results obtained are trustworthy and whether the treatment described really resulted in the behavioral change found. When research evaluation leads the consumer to conclude that the weaknesses are insurmountable and the results suspect, these studies should be ignored. The rest will fall along some continuum from merely adequate to excellent. Research that is strong in all areas can be applied with more confidence than that with many weaknesses.

Figure 1 includes a list of questions that may be useful in evaluating research articles. Various sources useful in gaining a conceptual understanding of the issues involved in research are listed in the annotated bibliography.

For research that is well-conducted and well-described, the next problem is application. It is obviously easier to apply applied research than research that is highly theoretical. Intervention studies and psychometric research are often directly applicable to daily practice. But basic and theoretical research may also be quite applicable, especially if it helps us understand how or under what conditions a treatment (or intervention) may be useful. Basic research comparing the effectiveness of various mnemonic devices for different types of subjects might be quite applicable to a student with poor memory skills, for example. The connection is not as direct, but a good mix of applied and basic research may be very useful in understanding a problem.

Sources for consumers of research. The primary source of research reports is journals with relevance to school psychology. A useful list of such journals is presented in Reynolds, Gutkin, Elliott, and Witt (1984, Appendix G). Conferences, conference proceedings, and the ERIC Document Reproduction Service are other outlets for relevant research, but these manuscripts are generally not as carefully reviewed as are those submitted to journals, so consumers of this research need to be even more critical than of journal articles. Research reviews and book chapters are another good source for both consumers and distributors of research. If well done, they provide a concise, objective summary of research knowledge in an area and their reference lists can provide good sources of the original research. These reviews and chapters may also provide a good conceptual introduction that will be useful when reading the original research. But like original research, the quality of reviews and chapters varies considerably; it is best to have some familiarity with at least some of the original research to be able to ascertain that the writer of the review did a competent job of summarizing the research.

If most school psychologists are to be consumers, rather than conductors, of research, then their concern when taking research courses should

FIGURE 1. Questions for evaluating research articles.

Is the purpose well defined?
Is the literature adequately summarized?
Does the introduction establish the need for the study?
Is the research design appropriate? Is it powerful enough so that you can trust the results?
Does the research design fit the purpose?
What type of research design is used (experimental, quasi-experimental, nonexperimental, single-case, etc.)?
Does the analysis fit the design?
How was the sample collected? Is it representative? Is it large enough to allow a good statistical test?
Is there evidence to support the reliability and validity of any tests or questionnaires used?
Are the results presented consistent with the purpose, the design, and the analysis?
Does the discussion flow from the results? Is it consistent with the purpose of the study?
Are the conclusions consistent with the results or do they go well beyond them?
Are the limitations of the research discussed?
What are the major strengths and weaknesses of the study?
Is the article well written?
Are the results of the study generalizable to your population? Are the treatments generalizable into interventions?
Is this research applicable to your work?

Note. These questions provide an overview of those aspects which may be important in evaluating research articles. They will not all be equally applicable for all articles.

be for a conceptual understanding of research. I believe there is one exception to this rule. All school psychologists should be able to develop rudimentary single-case research designs. It may not be feasible to expect all school psychologists to conduct complex single-case research (although such research is more applicable to applied settings than are most types of research), but knowledge of such designs is useful because they can be used to evaluate the effectiveness of virtually *any intervention* — behavioral or otherwise.

An example: Using research to develop an intervention. As an example, a school psychologist is referred a fifth-grade boy, Sam, who is having trouble keeping up with his peers. The teacher does not think Sam is a candidate for special education but does want assistance in helping him deal with what appears to be a relatively mild learning problem. Assessment and a review of records supports the teacher's suspicions: Sam has never been a star student but he has never experienced serious problems before either and has not previously been referred. He appears to have slightly below-average abilities and achievement in a generally high-achieving school. Assessment also suggests that Sam, his teacher, and his parents are all fairly motivated and would be willing to cooperate with some sort of intervention.

The school psychologist has read several articles recently on the effects of homework, and it occurs to her that homework might provide the basis for a cooperative home/school intervention. A cursory review of research suggests that homework is effective for this age group, especially so when it is commented on by the teacher and when current homework demands are small (e.g., Keith, 1987). Further investigation reveals that the teacher currently assigns little homework, and thus a homework intervention seems a likely possibility. Additional reading suggests worthwhile features of effective homework interventions (Miller & Kelley, 1991).

The psychologist begins conducting curriculum-based assessments in Reading (e.g., Deno, 1986) and charting Sam's weekly quiz grades in math and spelling. In cooperation with the teacher and the parents she plans a homework intervention: The parents will provide a quiet place for Sam to study at a regular time each day; the teacher will eventually provide daily, individualized homework in at least two of the three areas being charted and, on a daily basis, will check the homework, comment on it, and provide feedback to the parents about its accuracy. The parents, in turn, will provide reinforcement at home for homework that meets an agreed upon, adjustable criterion of accuracy (as reported by the teacher).

Because the psychologist wants to ensure it is the intervention, rather than some other, uncontrolled influence that causes any subsequent change in Sam's achievement, she designs the intervention as a multiple-baseline design across school subjects. Homework in reading is introduced first, although performance in all three areas continues to be charted. If the intervention is effective, she might expect to see improvement in reading after a few weeks of the homework intervention while spelling and math grades stay at about the same level. Homework could next be introduced in spelling and, after progress was shown, in math. Of course, if the homework seemed effective in reading, the teacher and parents might be tempted immediately to begin homework in the other two areas, but they would need to be cautioned against jumping the gun. By conforming to the multiple-baseline plan, the psychologist can feel confident that the intervention, not something else, is causing any change in Sam's behavior. This knowledge is important because it provides information that may be useful in future interventions with Sam and other students and because it ensures that Sam, his parents, and his teacher are not completing all of this additional work for no purpose. This approach has the added benefit of introducing the intervention gradually and of providing data that may be used to make needed changes in the intervention. The approach is not a sophisticated single-case design, but it would provide evidence of the effectiveness — or lack of effectiveness — of the intervention. It also illustrates the connections among research, assessment, intervention, and evaluation. It should also be noted that a wide range of outcome measures (behavioral and otherwise) are possible in single-case designs. For example, if we were interested in the teacher's impressions of Sam's preparation for class, we could assess this possible outcome using a simple rating scale. These daily ratings of preparedness in the three subjects would also fit well in the multiple-baseline design.

Improving skills: Consumers. Most school psychologists have had all or most of the training necessary to become effective *consumers* of research; what they need is to improve and use the skills they have. The books and articles in the annotated bibliography may help refresh that training, and they approach research more from a conceptual than a numerical level. Consumers should also read research regularly and attend research presentations at conferences. We should be interested in the results of research, but always approach it skeptically. As Reynolds and Kaiser reminded us, our attitude should be "In God we trust; all others must have data" (1990, p. 487).

Of course, if school psychologists are to be effective consumers of research, their employers must recognize this as a part of the job. In my experience, many employers are pleased when their psychologists try to base their practice on solid research, provided that the knowledge (a) does not cost a lot of extra money and (b) is not used as a weapon with which the psychologist battles policies of the administration (as in, "Well, the research says this program the superintendent started up last month is not very effective"). As with any new role, this process might have to be started through an investment of one's own time rather than the employer's: When you can show some payoff — for example, through effective interventions — your employer will be much more willing to recognize the value of the research consumer approach.

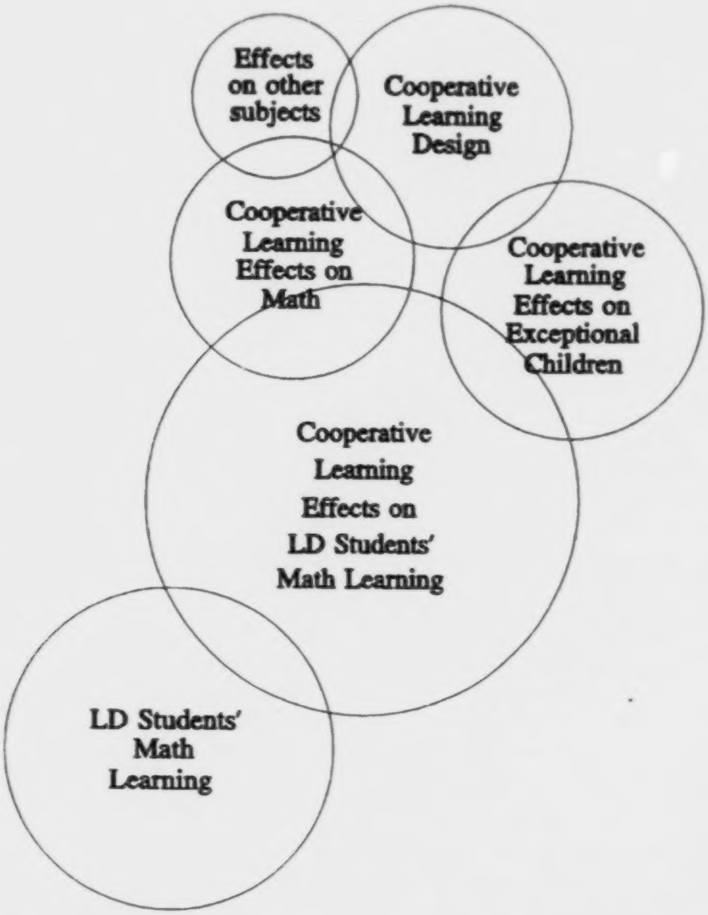
Distributors

Integrating research findings. Distributors of research consolidate and integrate research findings in order to draw conclusions from that research and make recommendations based on those conclusions. To do so, distributors first need access to a body of research, and probably a wider access than do consumers of research. Distributors need to be able to define their research topic so that their review is neither too broad nor too narrow. I find it helpful to organize research topics as a group of overlapping circles. For example, if I were interested in the effects of cooperative learning strategies on the math achievement of students with learning disabilities (LD), I would want to read and evaluate research that directly addressed that question as comprehensively as possible. Thus, my central topic — and the central circle in Figure 2 — is research addressing the effects of cooperative learning on LD students' math achievement.

I would also be interested in several related topics, such as the effects of cooperative learning on other types of exceptional children's achievement, the effects of cooperative learning on normal children's math achievement, and other important aspects of math learning in LD children: These topics are represented by circles that overlap the central circle. Although each of these related topics is of interest, they are less central to the main topic of interest and therefore my reading of research in these areas would not need to be as comprehensive. Much of my information about these topics could even rely on review articles, if they were well done, comprehensive, and recent. The next set of circles from the center might include such topics as the effects of cooperative learning strategies on other subject areas and the design of cooperative learning strategies: while these topics should be considered, they might receive only a cursory review. Thus, although my reading should cover all important aspects of the problem, I would spend less time on research less central to my research question.

Like consumers, distributors of research need to be able to evaluate the research they read. In fact, this

FIGURE 2. Topics included in a review of the effects of cooperative learning on the math achievement of students with learning disabilities (LD). The farther the circle is from the center, the less extensive the review.



Effects on other subjects
Cooperative Learning Design
Cooperative Learning Effects on Math
Cooperative Learning Effects on Exceptional Children
Cooperative Learning Effects on LD Students' Math Learning
LD Students' Math Learning

skill is even more important for distributors because they need to cover the research more thoroughly and are therefore more likely to encounter contradictory research findings. Distributors need to weigh better research more heavily in making conclusions. That is, they should base their conclusions primarily on the better research, only using the medium-quality research when it addresses important questions unanswered by better conducted studies.

Probably the most difficult part of consolidating research is *integrating* diverse research findings. The least useful review of research is one which simply lists in separate paragraphs the findings of each research study. Instead, the goal of a research review should be to combine and *integrate* the various research findings in order to draw one or several conclusions (with appropriate caveats) from the research. One rule of thumb is to avoid making the *researchers* the subject of a sentence or a paragraph, but rather to focus on the *findings* of research and make most citations to researchers parenthetical. For example, a hypothetical sentence might read that "coursework appears an important influence on student learning (Anderson, 1991), whether learning is measured by test scores (Smith, 1988) or by grades (Jones, 1987)." This sentence integrates the findings of three hypothetical studies. In contrast, I might have written: "Smith (1988), in a regression analysis of 867 high school students, found that the coursework taken by those students had a strong effect on their subsequent achievement test scores. Jones (1987) studied students in academic versus general high school tracts and found that . . ." and so on. The first method integrates the findings; the second method treats them separately.

Quantitative research synthesis, or meta-analysis, is becoming increasingly common and can be a valuable tool for research distributors. Even those who do not use the quantitative methods of meta-analysis can profit from a discussion of the considerations necessary for valid research synthesis (e.g., Wolf, 1986).

The steps listed previously as important in distributing research are the same steps involved in a literature review: review an appropriate body of research, integrate the findings, and make conclusions. Distributors of research need to take this process one step further, however. They are presumably conducting a research review because they wish to bring research findings to bear on some practical problem; they also are conducting the review to share with others. As a final step in such a review, a research distributor should be able to make recommendations for action based on the conclusions drawn from research.

Sources for distributors of research. Research distributors need a wider access to journals and other sources of research than do most consumers. In addition to school psychology journals, distributors need access to journals from educational psychology, special education, behavioral, and counseling and clinical psychology. Distributors also need access to other sources of research (e.g., conferences, ERIC abstracts, books) and they should be able to integrate basic, theoretically oriented research with applied research.

Fortunately, the "legwork" required of research distributors — conducting searches of the literature, finding relevant articles and books — is becoming easier and easier. Most university libraries now have data bases of research articles on CD-ROM. For example, ERIC and PsycLit on CD contain 10 years or more of abstracts and publication information from education and psychology journals. It is easy to search multiple journals quickly for keywords of interest; the results of the search can then be downloaded to floppy disk or printed. Obviously, these new "instant" searches can be a great starting place for research distributors.

Much of the work involved in distributing research can be completed before a visit to the library. Research distributors with access to the *Internet* computer network can search the holdings of most university libraries in the U.S. (and many outside the U.S.) from their home or office. ERIC and PsycLit searches are available through the Internet, as is a service (CARLUNCOVER) that allows the search of the titles of articles from over 14,000 journals. With CARLUNCOVER one can also order articles of interest, for a fee. Research distributors interested in such services should contact a local university library for more information. Most universities are connected to Internet, and access to Internet is also available through most commercial electronic networks (e.g., Compuserve).

Improving skills: Becoming a research distributor. Psychologists interested in improving their research distributing skills may also profit from the books and articles listed in the bibliography. Also, they should develop the practice of critically reviewing the research they read and study research reviews written by others. One excellent way to practice reviewing research is to serve as a referee for articles submitted to journals. Most journal editors are eager to find colleagues willing to serve as occasional reviewers for research and review articles submitted for publication in their journals (and editors of school psychology journals are often especially eager to find practitioners willing to review articles). Most journals use anonymous reviewing (the reviewer does not know the identity of the author) in order to ensure honesty in reviews; however, courtesy should not be sacrificed as a result of anonymity. Serving as a reviewer provides practice and often feedback; most editors send each reviewer the comments of the other reviewers in addition to their own blinded letter to the author.

Without realizing it, most psychologists hear questions amenable to research review constantly, from parents, teachers, and administrators. Do you think young boys should wait an extra year before starting kindergarten? Should I give homework to second graders? Does ability grouping harm low-achieving students? Should we institute a cooperative learning program in the elementary schools? All of these questions address educational topics that have been the focus of research, and answering those questions may be easier with a solid understanding of what research says about the effectiveness of the programs in question. Psychologists who wish to add the role of research distributor to their jobs can begin by volunteering to help provide answers to questions of interest to their school district or other employer, or by volunteering to serve on policy-making committees. For example, district-wide policies on homework are becoming popular; a psychologist serving as a research distributor could provide valuable information to a policy-making committee on the effects of homework on student learning.

Conductors

Designing and conducting research. Conductors of research first need to be competent consumers and distributors of research. Beyond that, they of course need to be competent in research design and analysis. Arguably, they also need another, often overlooked skill: They should be able to transform vague questions of practice and policy into general research questions. In my experience, the most common mistake made by inexperienced researchers is that they tend to focus immediately on the details of a study (the sample, the statistics to be used); a common mistake made even by experienced researchers is that they have vague or poorly defined research questions. The missing step in both cases is to go beyond the vague questions that led to an interest in the topic being studied and to derive *general, testable* research questions. Do you wonder what can be done to best educate disadvantaged youth or whether low-achieving first graders should be retained? These vague questions of policy can be phrased as research questions is a variety of ways, each of which would lead to a slightly different research design. I find it helpful to force myself to phrase these vague questions as questions of 10 words or less, usually in the form of does *x* affect (or improve or influence) *y*? Does grade retention improve later achievement? Does an academic curriculum affect disadvantaged students' future economic success?

Once the general question has been phrased, conducting research is simply a matter of making choices (how do we define disadvantaged?) and compromises (should we use a small, but intensively interviewed local sample or a larger regional sample with less information per person?) With practice, you will find research questions popping up everywhere — as a result of normal conversations, articles in journals, newspaper stories and editorials, and other unlikely sources (for example, the seed for my question about educating disadvantaged youth was planted by an article in *Reader's Digest*).

Conductors of research also need competence in a variety of research designs to ensure that the design chosen indeed tests the research question asked. *Expertise* in research design is not necessarily needed if you are willing to collaborate or seek the advice of someone with that expertise, but a broad understanding of research designs is needed. In particular, competence is needed in research methods that are appropriate in applied settings but which may not be stressed in a typical graduate program: quasi-experimental, single-case, and nonexperimental designs, along with psychometric methods.

Similarly, conductors of research need a general, broad competence in analysis to ensure that the method of analysis is congruent with the research design and the research question. For any sort of statistical analysis one needs access to a good statistics computer program. There are a multitude of programs available for personal computers, ranging from simple to complex and from cheap to expensive. Reviews of programs are one source for help in choosing a program and are becoming more commonplace in professional journals and computer magazines. For example, *PC Magazine* recently reviewed and compared 13 statistical programs ranging in price from $125 to several thousand dollars (Canter, 1993). Beyond reviews, one needs to look for a program that computes the statistics wanted, is easy to use, is widely used, and is regularly revised.

One option is to use one of the major programs derived from mainframe statistics packages (e.g., SAS or SPSS). These programs are widely used and regularly updated, and so one may have confidence that any errors will be quickly spotted and remedied. Unfortunately, these packages also tend to be the more expensive and largest programs available. Fortunately, there are many less expensive programs available but, again, care is needed in choosing a program that is accurate and easy-to-use. Statistical programs are increasingly becoming required purchases in statistics classes and are often available at a considerable discount through such classes; the opportunity to purchase a good program at a low cost may be an extra benefit for anyone planning to take a new or refresher research class.

Conductors of research also need competence in communicating the findings of research orally and in writing. Nothing spoils a good piece of research faster than a report of that research that is poorly written, vague, or full of jargon.

Improving skills: Becoming a research conductor. Many psychologists have the knowledge necessary to conduct research, and most have, or could easily have, access to data that would be useful for research purposes. School psychologists are awash in data — test scores, ratings, observations — much of which would be ideal for research purposes with a little prior planning. What is generally missing is *practice* doing research; even school psychologists who have completed a thesis or dissertation often do not feel comfortable with the process of doing research. If this assessment is correct, what psychologists — those with the necessary requisite skills — need is to work with, or even serve as apprentices to, others who actively are conducting research.

Probably the easiest way to develop a research apprenticeship is to contact faculty in school psychology or related areas at a local university. Most faculty at universities with graduate programs are expected to carry on a program of research as a part of their jobs; most would welcome help in data collection, analysis, writing, and the other tasks of research, especially if you can provide a source of data and are interested in answering research questions that are of interest to them. Another option is to work with others at a local level who are doing research. For those interested in serving as an apprentice, proximity is important in order to experience all aspects of research. For those who already have research experience and who are looking for research collaboration, proximity may not be as important. With computers and electronic mail (even with regular mail), long distance collaboration is quite possible and increasingly common.

The best way to have the role of conductor included as a part of your job description is essentially the same as for a research distributor: Volunteer to find the answer to a research question that evolves from a problem facing your school system (or mental health center, etc.). If your research will answer a question of interest to your employer, not cost a lot of money, and not interfere with your other responsibilities, you will probably be welcome to conduct it. It may take a commitment of your own time in the beginning, but if you can prove your worth as a research conductor, your employer will begin to see this role as a part of your job.

SUMMARY

All school psychologists should be involved in research, although there is little need for most actually to conduct research. All psychologists need to be effective *consumers* of research; they should be able to read critically research that has implications for their practice and incorporate the findings of that research into their practice. A smaller number of psychologists are needed to serve as research *distributors:* They summarize the findings of relevant research and convey those findings to their colleagues and employers. A still smaller number may be interested in actually *conducting* research: They should be able to design and conduct studies that answer research questions of interest to themselves and their employers. It is not particularly difficult to serve in any of these roles, and advances in computers, software, and electronic networks have made these research roles available to a much wider audience. As with any new role, the hardest part is getting started.

ANNOTATED BIBLIOGRAPHY

Barlow, D. E., & Hersen, M. (1984). *Single case experimental designs: Strategies for studying behavior change* (2nd ed.). New York: Pergamon.
This comprehensive book is an excellent reference for single case research methods.

Huck, S. W., Cormier, W. H., & Bounds, W. G., Jr. (1990). *Reading statistics and research.* New York: Harper Collins.
This fine book was originally published in 1974; it was reprinted, but not revised, in 1990. The book is intended primarily for people who want to read and understand the research of others (here called research conductors and distributors). It presents statistics and research designs from a conceptual standpoint and, although quite dated, does a nice job of demystifying research. It also contains a nice introductory chapter on single case research.

Keith, T. Z. (1988). Research methods in school psychology: An overview. *School Psychology Review, 17,* 508–526.
This article provides a conceptual overview of diverse research methods used in school psychology, with a particular emphasis on understanding the power of different methods for inferring that a research treatment produces an outcome.

Kerlinger, F. N. (1986). *Foundations of behavioral research* (3rd ed.). New York: Holt, Rinehart & Winston.
Kerlinger's book is probably the best single book on research; his is primarily a conceptual, theoretical approach, although he does not shy away from numbers. Despite some unevenness of coverage (single-case designs are not discussed; the presentation of LISREL is overly-enthusiastic), this is a very thorough book.

Phillips, B. N. (1990). Reading, Evaluating, and applying research in school psychology. In T. B. Gutkin & C. R. Reynolds (Eds.), *The handbook of school psychology* (2nd ed., pp. 53–73). New York: Wiley.
Phillips presents a variety of issues pertinent to research in school psychology, written primarily for consumers and distributors.

Best Practices in Maintaining an Independent Practice

Steven L. Rosenberg
PSI Associates, Inc.
Twinsburg, Ohio

OVERVIEW

Many school psychologists are loath to consider such economic concepts as "cash flow," "market niche," and the "law of supply and demand." Even in our free-enterprise open-market economy, considered a touchstone symbol of our Western civilization, to think of a *return on investment* is often viewed as somewhat distasteful and distant from "professional psychology." Success in the independent practice of school psychology demands a realistic view of the free enterprise system. Would-be practitioners must come to terms with these forces if they are to succeed. One prerequisite requires the psychologist to shrug off the baggage of emotions that equates independent practice with something that is somehow unclean, dishonorable, and parasitic. This may well overstate some public providers' disdain for private practice. Yet, the successful independent practitioner recognizes that it is equally as worthy and "professional" to provide services for fair and direct remuneration, as it is to be paid indirectly from the public purse through service to schools. Medicine, for example, has come to terms with dual systems of public and private service without any implications of hierarchy. (However, where a hierarchy is assumed, then independent practice is frequently seen as *higher status* than service as a hospital doctor.) Psychology would come a long way by emulating the mature perceptions of independent practice as seen in accounting, medicine, and law.

With a PSI Associates, Inc. colleague, Donald M. Wonderly, I prepared a chapter for *Best Practices in School Psychology–II* dealing with the early stages of developing an independent practice (Rosenberg & Wonderly, 1990). That chapter describes some of the pitfalls awaiting the psychologist naive in business matters and offers suggestions for hurdling problem areas. "Establishing an Independent Practice" describes some of the considerations basic to setting up a business selling professional services, including *finances*, *planning*, selecting the *product* of the service, *promoting* the business to referral sources, and *locating* the business. Space was given to the issue of *price* and *fees:* How much should I charge, and how do I collect the fees? Many psychologists new to business are frankly uncomfortable with anything to do with collecting a fee for the work they do. However, these same people are adept at spending the very dollars they find tough to collect. For example, many psychologists learn to their chagrin the extraordinarily high costs of engaging front office help (such as a receptionist and secretary); office, furniture, and equipment lease fees; and similar expenses of initiating a business. Consequently, in that chapter I detailed many of these costs, including

- Payroll taxes, rent, utility and telephone charges.
- Tax and legal representation and consultancy.
- Insurance (general liability, professional liability, fire, theft), professional membership, salaries for employees, health and life insurance, retirement contributions, postage, printing and travel.
- Furniture, equipment and office supplies.
- Interest costs (lost or incurred) on funds used to float the business.

Thus, the chapter "Establishing an Independent Practice" provides a starter kit for the psychologist considering a venture into the business arena. This present chapter develops on the earlier discussion about creating a viable business by considering issues that have increasing importance as the business matures.

BASIC CONSIDERATIONS

Entrepreneurship: Can It *Ever* Be "Professional"?

An independent practitioner's attitude towards entrepreneurship is a key ingredient if an independent practice is to grow (or even be maintained successfully). Unfortunately, most school psychologists are unfamiliar with the principles of business and finance and are disinclined to accept conceptualizations associated with the *business* operation of an independent practice. In fact, an entrepreneurial orientation many times conflicts with values held by publicly employed school psychologists.

Unless the would-be practitioner plans to open the office and merely wait for the phone to ring, he or she must reckon with such concepts as market niche, competition, profit margin, "bottom line," and salespersonship. Many of these concepts can be learned. A bounty of legal and financial consultants (caveat emptor) are available to "assist" in all these matters. Their help notwithstanding, it is imperative that the practitioner be prepared to cope with an entirely new set of demands upon time. Business considerations *must* be successfully dealt with if financial and professional goals are to be realized, and commitments honored.

Independent practitioners of school psychology must also be prepared for the reactions of peers, especially as the enterprise becomes successful. It is as common as it is ironic that publicly employed personnel are critical of their private sector counterparts. Unlike private practitioners in medicine, dentistry, and law, independent practitioners of school psychology are generally *not* held in high regard by their peers. This is especially true of the practitioner who works in nontraditional settings. Contractual, and similarly innovative delivery models typically ruffle the feathers of conservative colleagues.

Such criticism is certainly common in the worlds of industry and commerce. Yet, it is more difficult for the entrepreneurial helping-professional to be the recipient of criticism and rumoring. This problem is compounded because there is no readily available forum to explain actions which are in question. High profile cases (e.g., custodial and forensic evaluations) and situations involving large numbers of individuals (e.g., employee assistance programs) can be particularly difficult, requiring skills foreign to school psychology preparation.

The practitioner must be ready and willing to deal squarely and responsively with many nonprofessional issues. What percentage of assessed fees are noncollectible? How are employees to be compensated? What employee benefits are appropriate? Which of these are affordable? Are employees to be paid whether or not fees are collected? What is the competition doing and how does it impact upon already established plans? What are the overhead costs (secretarial, rent, payroll rates, postage, printing, supervision, advertising, taxes, etc.)? How long can financial commitments be met with a lower than expected income stream?

These are but a few of the innumerable issues independent practitioners must address. Ignoring them, with a focus only on the professional issues associated with school psychology, has destined many an enterprise to fail. Competent and efficient professional services are a necessary but insufficient recipe for developing and maintaining a successful practice. Such skills must be blended with a sound business and financial orientation to increase the probability of success. Only in this way can the entrepreneur avoid many of the common trapdoors which cause an inordinate number of young professional businesses to fail.

Targeting Your Marketplace

It is critical for the "would-be independent practitioner" to clarify the "market niche" to be served. As the supply of qualified psychological personnel grows, it becomes more important to narrow the scope to serve an otherwise unserved or poorly served population. While historically the traditional "Jack-of-all-trades" psychological provider has been successful (and still may be successful in high-demand situations), one's chances for success are enhanced by offering a clearly delineated specialty that is in demand. Paradoxically, such a specialty must, of course, also be broad enough to generate sufficient referrals to satisfy cash flow requirements.

The best and perhaps only genuine way to determine your specialty is to analyze your talents, training, and skill levels in every way possible. Introspection and feedback from fellow professionals that identifies with which of your clients you were most successful are critically important first steps. Self-critique can save the possibility that you will target a market which seems novel, attractive, and of high interest — but one where your skills are insufficient to generate the reputation needed to develop a niche. Once this professional focus is narrowed, you must investigate whether there is a local market which demands your services.

Common sense, professional propriety, and ethical canons clearly demand that your final determination of a specialty be demonstrably within your areas of training and expertise. Further investment in academic and professional experience is rarely justifiable to help make the final decision as to your area of service.

One of the principal difficulties in maintaining success in independent practice is attracting a steady flow of clients. Contributing factors include (a) inadequate or inaccurate information about your services, (b) clients' prior negative experiences with mental health providers, (c) clients' resistance to the notion that one benefits from psychological service, and (d) its cost. The impact of this last factor becomes more severe as third-party payors reduce, restrict, or even eliminate coverage to school psychological services. The first and last of these four factors are perhaps most amenable to your creative problem-solving efforts, while solutions to the other two result from your growing positive reputation.

Even those practitioners who rely on the relatively conservative marketing stratagem of accepting referrals from other professionals discover obstacles. Referring parties may fear the competition your services seem to represent. School psychologists suffer from a poorly-defined image. The assumption is often made that your services are unnecessary, unimportant, or redundant with the services of providers in related fields. Already-established referral patterns to other professionals can also interfere and will persist as a barrier to the success of your practice unless you can market your services to other professionals as uniquely responsive to their clients' needs. Growing a successful independent practice depends in large part on the quality and dependability of your referral sources. This often misunderstood concept causes many fledgling practices to falter and fail. Rather than concentrating on office color schemes and floor plans, the wise entrepreneur cultivates appropriate and reliable sources of referral.

The neophyte independent practitioner must diligently develop a viable network of referring sources. Once the targeted client population has been identified, an exhaustive list should be developed of all available sources of referral. Many of these potential sources will be easily accessible; others may demand more creative approaches to establish contact. Sufficient time and energy must be invested to explore every available avenue: Family doctors and pediatricians, the family dentist, and attorneys with whom you are acquainted are examples of ready contacts as are speech and hearing therapists who work independently or who are part of an agency or center, and social workers employed by government agencies to work with children. Publicly employed school psychologists represent potential and valuable sources of referral. Each of these professionals should be encouraged to suggest others in their network for contact.

Even for a part-time practitioner, no single referral source can be depended on to keep a practice busy. A variety of referral sources must be garnered for the independent practitioner to be successful. Many components are necessary if a potential referral source is to become viable. However unfortunate it may seem, competency itself is insufficient to ensure the success of an independent practice.

There are a number of other factors every entrepreneur must consider. First and foremost, the purchaser of services, or the referring professional, must have confidence in the provider. There must be a belief that valuable services will be forthcoming. Confidence develops slowly. Trust is on a shaky foundation when it's based on an embellished claim of prior therapeutic successes. Rather, such assertions are usually transparent; for they plant seeds of mistrust that are, at the very least, counterproductive and unethical. The practitioner needs to present a menu of services in a responsible and accurate manner that engages the interest of a would-be referral source.

What services can be provided that differ from those offered by others? Can more in-depth follow-up be provided? Can office hours be tailored to client needs? Can the geographic distribution of other independent practitioners be exploited so that your office location will offer greater ease and convenience? Can the services of a variety of related professionals (e.g., speech, nursing, medical) be offered within the same office complex, enhancing the ease of referral by busy physicians, school administrators, and the like? Are your service costs comparable to competitors' rates? Can fees be structured to be appealing to potential clients (per hour, no charge initial consultation, etc.)? Consider in what form referring sources would most prefer feedback. Are they inclined to participate in your treatment, or do they wish to be "out of the loop"? Are there special financial considerations (e.g., graduated payment schedules)? When a referral source is satisfied with the services, can that individual be gently encouraged to pass your name on to other colleagues? The importance of developing competent referral systems cannot be overstated.

A thorough evaluation of the competition offers the innovative psychologist innumerable ways to position an independent practice. What is "the other guy" providing that can be done better? Why should potential referral sources select your practice instead of more established ones? In what ways can your services be distinguished from others?

While these questions are difficult, success depends upon the quality of your answers. In a world of ever increasing privatization, deregulation, and free enterprise, school psychologists wishing to break into the potentially rewarding world of independent practice must cope successfully with these issues.

Learning from Colleagues

During 1987–89 I chaired the Independent Practice Task Force of the National Association of School Psychologists (NASP). As a "flagship" activity for this group we conducted a NASP preconvention program, part of which provided insights into some of the reasons why independent school psychology businesses fail. The obstacles are many and varied; nonetheless, there are patterns to be discerned and overcome, regardless of states' regulations and the specific limitations on particular professionals.

Issues associated with insufficient client recruitment, excessive financial commitment, an oversupply of service providers, and a lack of business acumen are of greatest concern. These must be squarely confronted for an independent practice to become successful. Failed endeavors usually faltered because of one or more of the following pitfalls: Poorly constructed goals and objectives; nonspecific service models; prematurely terminating secure employment to pursue potential independent practice income; and incurring unnecessary expenses.

It is common for school psychologists to initiate an independent practice without a clear and concise foundation of goals and objectives. Which client population shall be served? How will referrals be obtained? Can potential sources be relied upon? What is the minimum number of billable client-hours each week needed to generate sufficient net income? What income can reasonably be expected after 12 months, 24 months, 36 months, and so forth?

It is also common for new practitioners to assume that the traditional fee-for-service paradigm is the delivery system of choice. However, successful entrepreneurs have first considered all the available options before committing themselves to one specific approach. Perhaps contractual services, of which there are many variations, can be an innovative and successful tactic. Novice independent practitioners as well as established practitioners wishing to expand their operations must consider all the available service models before committing to one. The invested time and effort inevitably pay dividends.

It *should* be surprising to learn about individuals who prematurely sacrifice secure employment to risk the rewards of independent practice. But that is not the case. This phenomenon is all the more astonishing since opportunities exist to establish a practice on a part-time basis without terminating school-based employment. Given the failure-rate for new businesses in general, and the independent practice of psychology in particular, every opportunity to learn about independent practice should be examined before walking away from a guaranteed income.

"Delusions of grandeur" among neophyte practitioners are not unusual. Upon obtaining the appropriate licensing credentials, school psychologists are often convinced that wealth and fame are just around the corner. Business cards and a "Yellow Page" listing seem all that stands in the way of success. However, the repeated stories of disappointment are indicative of the significant obstacles facing would-be independent practitioners.

The prospect for disappointment is reduced in direct proportion to the accumulation of business knowledge and experience. Since most school psychologists are unaccustomed to the intricacies of the hidden costs of doing business (e.g., payroll taxes, utilities, telephones, service contracts, secretarial costs, postage, general and professional liability insurance, employee benefits, rent, etc.), consulting knowledgeable individuals is an essential step. While well trained accountants and lawyers can be expensive, they may save untold dollars and aggravation. Other resources can be tapped. Older, more experienced psychologists can serve as consultants. The Council of Small Business Enterprises (COSE) provides a link to low-cost or no-cost "senior" consultants willing to mentor fledgling entrepreneurs. The time involved in meeting with a successful professional to learn about reliable strategies and methods can be very valuable. Being an "apprentice" for such a practitioner on a full or part-time basis can be exceptionally educational. Finally, your public library has a wealth of books devoted to entrepreneurship, many of which have sections relevant to the independent practice of school psychology.

Rent is one of the main expenses to consider. Perhaps office sharing, an "incubator office" (i.e., per hour rental), or working from your home should be the first approach. Fancy offices with secretaries come *after* success, not before. While the appeal of paneled offices is understandable, independent practice should be approached with the utmost caution. Far more important is the analysis of expected income and expenditures. The number of clients needed per week to pay the bills must be calculated. Will the necessary number of clients continue indefinitely? How many of those clients will pay their bills in full? In a 40-hour week how many "billable hours" of client contact are possible? (Incidentally, even the most successful independent psychologist averages fewer than 25 billable hours weekly.)

The world of independent practice can be exciting, fulfilling, and rewarding. It can be entered with low risk and relatively low cost. It is crucial, however, for the practitioner to be a cautious business person.

Methods for Growing the Independent Practice:

Public exposure. One of the most common methods for building the practice is to actively seek opportunities to address the public. Well-prepared presentations on topics within one's expertise is a low cost but potentially highly productive method of gaining appropriate recognition. Presentations to public service groups are easily arranged. Radio and local television (i.e., cable) stations often look for articulate guests who are knowledgeable about high-interest topics. Hospital and philanthropic associations (e.g., Kiwanis, Lion's Club) often have Speaker Bureaus who may be receptive to your presentations. For the professional who is a satisfactory speaker, only time, energy, and initiative are necessary to arrange for many public speaking engagements.

Telephone directory advertisements. Most "Yellow Page" directories contain a lengthy section devoted to psychology. The entries range from discrete announcements to global claims of "anything cured." While the significance of phone directory advertisements is often overstated, they can provide for easy and convenient advertising. It is important to carefully review the cost of these ads and to consult with the appropriate state agency (e.g., your State Board of Psychology) to ensure that your entry is in accord with current professional standards and regulations.

Workshops. Constructing and implementing a successful workshop is very challenging. Enrollment and cost factors are difficult to overcome. However, if the practitioner is able to discover a niche previously unserved — but one in need of attention — then there are multiple professional and financial benefits from presenting workshops. The odds of successfully operating an independent practice are greatly enhanced if the practitioner's skills and reputation are widely known. It is wise first to contact family doctors, lawyers, and other well-placed professionals to learn what issues would be of greatest benefit to their clients. Workshops are an ideal way to match areas of expertise with community needs at a relatively low cost.

As many practitioners will agree with these notions as will disagree. Review them, adjust them, and then implement those with which you agree. Successful entrepreneurship demands affordable innovation and experimentation. After careful consideration, aggressively execute your chosen plans and methods to determine their viability.

Can Ethics and Business Goals Conflict?

Every business enterprise entails an element degree of risk. One ever-present danger concerns the possibility of litigation resulting from charges of malpractice. Although we rarely hear of cases actually brought to court and even less frequently of actual verdicts against a school psychologist, even one legal judgment can, if not ruin a career, seriously damage financial assets and impugn professional reputations.

It is impossible for a professional to be completely protected from legal action. The popular adage "anyone can sue anyone over anything" is well worth remembering. Whether a case can be won, of course, is a different matter. Yet, the legal fees, the inconvenience, and the harm to one's reputation can be very discouraging — even for those who win! While there are many steps that an independent practitioner can take to minimize legal risks, they can never fully be eliminated. All independent practitioners must face the fact that any professional contact may result in some form of legal action.

The obvious first step to reduce the chances of sustaining severe damage from litigation is to secure a competent and appropriate professional liability insurance policy. The premier ethical rationale for obtaining such coverage is that the policy protects our clients from our own misdeeds. In addition, it may save an unfortunate psychologist from incurring a ruinous debt which can wreck a family's financial security. While many attorneys (and even insurance agents in a candid moment) will admit that the very existence of professional liability insurance policy is an inviting target encouraging litigation, most professionals obtain some form of coverage. Independent school psychological practitioners must be careful to ensure that their policy covers work in a private setting. Policies utilized by publicly employed school psychologists typically exempt from coverage private practice.

Although it is always helpful to listen to the insurance agent's explanation of the benefits being purchased, it is vital to remember that insurance companies are not bound by the agent's assertions. Therefore, the entire policy must be read thoroughly. If you are unsure of its meaning, obtain written clarification from the underwriter. The onus is on the purchaser to be secure that the policy covers what is important. Examine the limits of the policy: Both the maximum paid for any individual claim, and the aggregate maximum that can be paid for all claims. Each practitioner must be comfortable with the limits purchased. It may be wise to discuss these issues with an objective third party such as a trusted attorney, accountant, or an established and experienced independent practitioner.

Secondly, every practitioner must remain vigilant to limit professional work to his or her area of expertise. While it may be occasionally challenging and/or opportune to provide service beyond one's own specialty area, to do so is not only unethical and unprofessional but also invites legal action by dissatisfied consumers.

Thirdly, each practitioner can alleviate a wide range of difficulties by being thoroughly and appropriately candid with clients: By comprehensively reviewing costs, the nature of the proposed treatment, and the expected length of time the treatment is intended to take. In this way, each client knows exactly what to expect. It is not uncommon for psychologists (as well as medical, legal, and other professionals) to provide clients with billing and other pertinent information in written form. Regardless of the method ultimately chosen, it is vital that clients are fully informed, thereby reducing the odds that any client will be surprised or angry — incentive enough to initiate litigation. Candor and honesty will serve any therapist well. High bills, excessive time commitments, and even less-than-successful therapy are *not* what angers the typical client. Instead, it is the client who feels he or she has been duped or taken advantage of. Hence, while it may feel awkward, it is essential to share appropriate information with every client early in the relationship.

The value of documentation cannot be overstated. Note when and what financial and prognostic information was shared with the client. Record the progress of treatment and any other important data shared with the client. These records can become an integral part of any legal defense. Many attorneys advise, however, that practitioners be circumspect in the information recorded in such "Clinical Notes." Many an unsuspecting therapist has had to review their "private" (sic) documents in the full and public light of the courtroom. However, there is no substitute for the appropriate recording of pertinent and relevant data.

Independent practitioners are guided by the profession's codes of ethics, state-level licensure requirements and laws, and published standards for service providers. A primary purpose of these guidelines is the protection of client welfare. In addition, practitioners find that adherence to such standards affords a degree of protection from claims of unsatisfactory of irresponsible service. Beyond familiarity with these principles, practitioners rely primarily on experience and advice to avoid the pitfalls associated with work whose success is so clearly dependent on the quality of the relationship between client and provider.

A recent article entitled, "Professional Liability Aspects of the Doctor/Patient Relationship" published by the American Dental Association Council on Insurance, discusses methods for fostering rapport and developing trust with clients. It contends that when the provider–client relationship is characterized by effective communication, the likelihood of client dissatisfaction — and potential legal action against the provider — is greatly reduced. However, this preventive philosophy does not always protect against dissatisfaction with, or failure of, treatment or client perception of case mismanagement. The report notes that certain types of clients and client behavior are associated with eventual legal action. Clients who pay their own bills, for example, or those who have been associated with providers for a short period of time, are more likely to sue. Client behaviors can also serve to warn practitioners of potential litigation. The article lists examples of such behavior: "Taking issue with . . . fees; Offering cash for a discount, particularly when a third party carrier is involved; Extra demands of time and attention . . . or the expectation of never having to wait for an appointment; The 'shopper'; The 'expert' (they see articles describing a particular technique and *that* is what they will get, either through you or through someone else who will do it)."

While providers need to be aware of these "warning signs," the solution to the problem of potential legal action does not lie in terminating relationships with clients exhibiting such behavior. On the contrary, such behaviors suggests a need for careful and extensive communication to ensure that misunderstandings or dissatisfaction are minimized or effectively managed. Risk management skills include several that are the psychologist's "stock in trade" such as listening skills (eye contact, body language, elimination of distracters, encouragement of questions) and speaking skills (avoidance of "psychobabble" and the use of clear examples). Other factors influencing the professional relationship are:

- The efficiency with which appointments are made, kept, or adjusted when emergencies arise.
- The style in which the provider's office is designed and decorated (outmoded furniture can suggest outmoded techniques; clutter suggests sloppy treatment and records management; expensive decor bespeaks exorbitant fees).
- The nature of written information (use of follow-up letters summarizing findings and plans; availability of newsletters or self-help/wellness pamphlets; provisions for telephone contact during crises; follow-up calls to referring colleagues).
- Record-keeping practices (procedures to safeguard confidentiality, including the removal of files from the view of waiting clients; preparation of neatly-typed and clear reports; release of reports in a timely fashion).

Finally, we must consider the importance of terminating the relationship responsibly and sensitively, regardless of the reason. If the relationship is terminated "prematurely," for example, the provider should help the client find alternative care and make records available to facilitate the transition. All clients should be prepared for the termination of services, with clear information about follow-up plans and recommendations. Truly capable and professional independent practitioners view the growing trend toward consumerism not as an annoyance or threat, but as an impetus for monitoring the effectiveness of their own policies and practices.

Certain types of intervention may seduce the psychologist into overstepping professional boundaries and ethical limitations either because of the hoped-for financial reward, or the thrill of engaging in more extensive work than is normally experienced within the parameters of traditional school psychology. Providing psychological services to children from disintegrating families is an example of "gray area" involvement.

Independent practitioners are often asked to intervene with children of separating, divorcing, or otherwise disintegrating families. In these circumstances children present a variety of diagnostic and therapeutic opportunities. Some of these interventions can be very valuable to the client. Others are more problematic. Evaluating the child's academic and personality factors associated with these familial difficulties are well within the areas of expertise typically included in school psychology training programs. Diagnosing the child's feelings toward his or her parents, their impact on the child's self-concept, and the ramifications these issues may have on school work, interpersonal development, and family interactions are equally appropriate and consistent with standard training programs.

For the child from a disintegrating family there are many issues that require training and experience additional to that normally received by the nondoctoral school psychologist. School psychology cannot be transmuted into "family therapy" simply because it is both needed and being provided independently. The decision to enter into such clinical areas should be made on a case-by-case basis, because situations and training programs differ dramatically. It is essential, however, for the practitioner to be keenly aware of his or her areas of expertise while remaining vigilant to continually steer clear of those interventions which may extend beyond formal levels of training and previously supervised experience.

The problem with treating children encountering divorce is that many *nonschool* psychological issues are liable to be associated with the child's problems (e.g., parental and familial dysfunctions). In addition, the school psychologist working privately with these children is likely to be vulnerable to legal entanglements in what are becoming virtually obligatory custody battles. While some school psychologists report that they feel challenged by the idea of engaging in "combat" with legal advocates, psychologists ill-prepared or operating beyond their areas of expertise frequently wish they had never allowed themselves to become entwined with the judicial system. Serving as an expert witness requires careful preparation and consultation with texts on the "how to" of expert testimony, in addition to a thorough clinical knowledge of the client.

Families undergoing divorce represent enormous opportunity for independent practitioners of school psychology. Offering therapeutic support groups, coping skills programs, and teaching parents methods they can use to reduce their children's anxiety, can be extremely valuable. Practically, however, it can be difficult for the clinician to have access to enough eligible children with similar problems within the right age range to make group arrangements successful.

Cultivating contacts with those directly involved with divorcing families can be very valuable. Divorce attorneys and domestic relations judges and referees, as well as mental health professionals within the justice system (e.g., those working in court-sponsored reconciliation facilities) can be good sources of referral. Approaching domestic relations attorneys, however, can be a challenging and daunting task, especially high powered lawyers with large divorce practices. The school psychologist should carefully select the attorneys to be contacted, always investigating reputations and specialties (e.g., women's issues), in an attempt to discover ways to complement the attorney's task or help provide their clients with a needed service. Clearly, finding a respected mutual acquaintance or professional known by both the psychologist and the attorney can only serve to strengthen the "referral bond."

While most "helping professionals" claim they feel capable of working with children of divorce, few specialize in this field. Therefore, one's professional persona may be enhanced by limiting to this work. Attorneys will respect this choice. A specialty concentrates the prospects for professional and financial success. Not only does it allow the practitioner to become truly expert, but affords the opportunity to be able to present oneself as a true specialist in an important and difficult field. Such specialization can provide the competitive edge, helping the psychologist become known as a skilled practitioner within this growing, but well defined subgroup — a very effective way to build a successful practice.

SUMMARY

Independent practice offers many intriguing and fascinating opportunities to the school psychologist who may be interested in working in nontraditional settings. The expansion of the role of the school psychologist and the chance to further develop professional skills are among the many benefits independent practice offers. Challenges are encountered on every front: ethical, professional, and financial. The rewards, however, can be substantial. To break away from the traditional psychometric mold, to operate with increased autonomy, to ply a wide variety of skills, and perhaps to reap financial reward are among the most desirable aspects of independent practice.

It is unfortunate that novice practitioners tend to focus on the glamorous rather than the essential components of independent practice. Without careful review, the psychologist risks far more than simply time and convenience. Reputation, personal assets, and self-esteem can be jeopardized. Only through diligence and knowledge is one apt to succeed.

Many psychologists attempting to grow their practice are overly concerned with such trivial issues as business cards and office color schemes. All one needs, they believe, are a signed lease, an ad in the telephone yellow pages, and of course, a secretary with a large appointment book. Data on failed businesses indicate that such an approach is foolhardy and dangerous. Many practitioners have found themselves with an exorbitant overhead and few, if any, paying clients. Such circumstances are both professionally embarrassing and financially draining. The tragedy is that such predicaments are generally avoidable. With foresight and knowledge, the school psychologist can be prepared and positioned to vastly improve the chances of success, while limiting risk.

Psychologists contemplating independent practice must evaluate their own attitude toward business. The concept of taking money in return for psychological services is anathema to many. However, unless one intends to offer services solely on a *pro bono* basis, receiving payment for service is crucial. The process becomes more difficult when clients already suffering from emotional distress are also of poor economic means. It is essential that the school psychologist growing an independent practice be fully prepared for what are considered the more unattractive aspects of the business. While exceptions can always be made in difficult situations, tough decisions must be faced.

The issues associated with independent practice are as varied as they are demanding. Regrettably, most school psychologists are ill-prepared competently to enter this field. Surveys of school psychology training programs' curricula demonstrate that it is rare indeed for programs to address independent practice. Yet with foresight, planning, and the necessary knowledge, the independent practitioner of school psychology can innovatively blend professional skills with entrepreneurship for the mutual benefit of the school psychologist and the client. Independent practice is a challenging, exciting, and sometimes remunerative field for appropriately prepared school psychologists.

ANNOTATED BIBLIOGRAPHY

Author Note: I know of no academic or technical treatise in the psychological literature on this topic. Academic libraries will rarely carry the following titles. However, most large bookstores carry them in a **Business** section of "how to" *trade books*. For this reason, I have provided ISBN numbers and current costs.

General:

Harper, S. C. (1991). *Starting your own business: A step-by-step blueprint for the new entrepreneur.* New York: McGraw-Hill. ISBN 0-07-026687-5. $12.95.

Sotkin, J. (1993). *Starting your own business: An easy-to-follow guide for the new entrepreneur.* Laguna Hills, CA: Build Your Business. ISBN 1-881002-84-5. $11.95.

Both are packed with explicit and specific recommendations based on proven experience from beginning business people. Best read in combination, they truly provide the step-by- step building blocks sought by the neophyte entrepreneur.

Hawken, P. (1987). *Growing a business.* New York: Simon & Schuster. ISBN 0-67167164-2. $9.95.

Companion to the 17-part PBS series of the same name — which is probably still available on video tape. Folksy and motivational in style, the book is not a "how to," rather, it illustrates business possibilities and pitfalls through experiences of individuals from widely differing fields. Emphasis is on marketing, customer-focus, and working to maintain repeat and referral business.

Witmyer, C., Rasberry, S., & Phillips, M. (1989). *Running a one-person business.* Berkeley, CA: Ten Speed Press. ISBN 0-89815-237-2. $12.00.

Comprehensive and practical for those planning on initiating or sustaining a solo business venture. While *not* restricted to *professional* businesses, most of the lessons are readily applicable by a creative school psychologist. Includes bookkeeping and financial strategies, information and time management, "setting up shop" (e.g., home vs. office base), the benefits and costs of solo business status, etc.

Incorporation:

Davidson, R. L. (1993). *The small business incorporation kit.* New York: John Wiley. ISBN 0-471-57652-2. $12.95.

McGuown,J. H. (1992). *Inc. yourself.* New York: Harper Business. ISBN 0-88730-611-X. $12.00.

Nicholas, T. (1992). *How to form your own corporation without a lawyer for under $75.00.* Dearborn, MI: Enterprise. ISBN 0-79310-419-X. $19.95.

Storey, M. J. (1993). *Taking money out of your corporation: Perfectly legal ways to maximize your income.* New York: John Wiley. ISBN 0-471-58043-0. $17.95.

In most states *professional corporations* do not have unlimited liability. Nonetheless, there are many benefits to incorporating the fledgling venture, including: In the case of economic failure the "loss" can be carried against other income, there are tax-reducing strategies unavailable to the sole proprietor, and several favorable tax-shelter retirement plans are only available to the corporation. Clearly, it is essential to get advice and oversight by a lawyer and accountant when deciding about incorporation; however, the information in these books can help you ask informed questions of your advisors.

Best Practices in Facilitating Team Functioning

Steven R. Shaw
Mark E. Swerdik
Illinois State University

OVERVIEW

In education, different types of teaming serve different purposes, including eligibility for special education services, development of individualized education plans (IEPs), periodic review of progress of children receiving special education services, co-teaching, site-based management, and problem-solving intervention teams. Each of these types of meetings can be collaborative problem-solving teams. This chapter will focus on increasing collaboration and improving the effectiveness of all team meetings. Collaborative teaming involves face-to-face interaction, shared leadership, effective communication, and individual and group accountability (Thousand & Villa, 1992). Most, if not all, types of team meetings can improve in creativity, productivity, and satisfaction if a collaborative approach is adopted.

Despite its intuitive appeal, the history of collaborative educational teaming for problem solving, planning, and program implementation is short. Its roots are found in legislated school improvement reforms, including site-based decision making (Glickman, 1990), ad hoc problem-solving teams (Skrtic, 1987; Thousand & Villa, 1992), teacher assistance teams (Chalfant, Pysh, & Moultrie, 1979), and collaborative planning and teaching teams (Thousand & Villa, 1992). Teaming recently has been promoted by those who advocate school restructuring and teacher empowerment. Some believe that teacher empowerment is increased through participatory decision making (Schlechty, 1990). Educational futurists, who have identified collaborative problem solving as a critical life skill for the twenty-first century, also have encouraged teaming in the schools (Wiggens, 1989). Students will then be able to observe educators value and model collaboration, and in many cases, participate in teaming. However, collaborative problem-solving teams are not common in today's schools.

Teaming has evolved over the past 50 years. Initially, the common approaches to service delivery were unidisciplinary; professionals became as competent as they could and served children without input from other professionals. Intradisciplinary teams developed as individuals within professions contributed to students' education. For example, a group of special education teachers may help each other to develop new intervention ideas for a child with a unique set of educational problems. Multidisciplinary teams (MDTs) involve a variety of professions (Maher & Pfeiffer, 1983). The members of MDTs recognize the importance of other professions in providing special services to children. However, each profession provides services individually, without integration. Most teams currently functioning in schools would be classified as MDTs. In most cases, traditional MDTs would not be classified as collaborative problem-solving teams. Interdisciplinary teams involve a variety of professions working together to develop jointly planned and implemented programs. Transdisciplinary teams involve a number of professions teaching, learning, and working with one another across professional boundaries. In a transdisciplinary team, a contact person handles most direct assessment, intervention, and parent contacts. The contact person may need to learn to administer curriculum-based assessment, conduct parent counseling, engage in occupational therapy, and conduct speech and language therapy. Other members of the team share their expertise by training the contact person to perform all of these roles (Patterson, D'Wolff, Hutchinson, Lowry, Schilling, & Siepp, 1976). In many states, the transdisciplinary model of teaming is not possible because roles are restricted by certification requirements and licensing laws. As models of teaming grow increasingly sophisticated, collaboration among and between professionals increases.

School psychologists have been involved in teaming primarily through the special education system. Special education has stimulated teaming in the schools through the MDTs mandated to conduct preplacement case studies, to determine eligibility, and to develop individualized education programs (IEPs) for students in special education. Multidisciplinary teams were required as part of legislation mandating free and appropriate public education for all children regardless of handicapping condition — namely the Education for All Handicapped Children Act of 1975 (PL 94-142), since reauthorized as the Individuals with Disabilities Education Act of 1990 (PL 101-476). However, MDTs that focus on classification and placement issues have been plagued by a variety of problems. The most significant problem is the lack of equal participation in decision making by some disciplines. Assessment personnel are given the most time and influence in these programs; educators participate relatively little in developing interventions (Ysseldyke, 1983). Many MDTs consist of cataloguing the student's problems and recitating standardized test scores and behavioral observations (Huebner & Hahn, 1990; Ysseldyke, Algozzine, & Mitchell, 1982). Instead of problem solving, MDTs frequently engage in problem admiring.

The Regular Education Initiative (REI), originating out of special education, emphasizes the value of building-based problem solving teams. The REI movement assumes that special education policies have created a fragmented system and that the regular educational environment has failed to meet the needs of a sizable group of students (Will, 1986). The REI movement has led to the idea of inclusive schools, where all children are taught in what has traditionally been called regular education (Ohio Department of Education, 1989). However, educational environments will need to be sensitive to the needs of children previously served by special education. A primary characteristic of successful inclusive schools has been a strong teaming approach for problem solving, planning, and program implementation (Schattman & Benay, 1992).

BASIC CONSIDERATIONS

Effective and Ineffective Teams

While team meetings can produce greater job satisfaction, more reliable educational decisions, reduce the likelihood of biased decisions, and are more likely than individual decision making to develop creative solutions to educational problems, this method also contains pitfalls. Team meetings present a host of potential problems: hidden agendas, chronically late or absent members, role rigidity, lack of trust, competitiveness, dominant or submissive members, a hierarchical structure of the team, diffusion of responsibility, and many other factors can dramatically reduce a team's effectiveness. Often a member of an ineffective team may believe that he or she can perform a task alone more effectively, without the team as a burden.

Members of effective teams report that team meetings are the highlights of their work day, cannot imagine having to perform individually the complex tasks addressed by the team, and believe that children receive better education due to the efforts of the team. Effective teaming requires more than collecting several educators in one room, however. Developing an effective team demands planning, patience, knowledge of small-group dynamics, interpersonal skills, unity of purpose, and continuous assessment of team effectiveness. Only by investing time in an effective team will creative and constructive work be accomplished.

Team Development

The Ohio Department of Education (1989) identifies five stages in group development. Teams that have been working together can expect to spend some time in each stage. These stages include (a) orientation stage — members are eager to begin and have positive expectations; (b) dissatisfaction stage — members may become frustrated that their early expectations have not been met and feel incompetent as a team and as individuals; (c) resolution stage — members develop realistic expectations and acquire more effective collaborative skills; (d) production stage — leadership is shared, and a sense of mutual interdependence with other members grows; and (e) termination stage — members feel a strong sense of accomplishment and are sorry that the team's work is ending. Effective collaboration demands a great deal of patience and effort. Understanding that all teams go through a period of frustration before becoming truly productive can be an incentive for continuing to invest in teaming.

Philosophical Orientation

Shared values and assumptions are important for effective teaming, although team members do not necessarily have to hold the same theoretical orientations (e.g., all behaviorists). These values and assumptions should be articulated and agreed upon before collaborative teaming is instituted in a building, and all building staff should participate in these discussions. The following lists assumptions that were adopted in a building in which one of the authors consulted; they are based on the work of Graden (1993).

1. All children can learn.
2. All students can experience some degree of success in school.
3. Learning does not require that all students complete all the tasks or even all of the same tasks of any particular unit.
4. Children's learning and behavior problems reflect the interaction between their own personal characteristics and their environment.
5. All children have a need to be a member of their peer group.
6. All children have a right to be included as a valued member of their family, school, and community.

7. Teachers play an important role in collaborative problem-solving to develop effective intervention strategies for students.

8. Teachers can develop new skills, acquire new knowledge, and with assistance develop intervention strategies to address the needs of students.

9. Team members can effectively plan interventions to address the needs of students.

10. A wide range of interventions should be available to meet a variety of student needs, facilitate student participation, and maximize student achievement.

11. Both assessment and intervention should relate directly to the needs of students and be classroom-based.

Whether the team decides to adopt these assumptions or some of its own does not matter. However, if members do not share the same assumptions about teaching and learning, then resistance to some interventions and poor integrity of treatment implementation will likely result (Elliott, 1988).

BEST PRACTICES

Process Variables

Leadership is important to the success of team meetings. However, we recommend a distributed functions approach unlike that of many traditional teams; here, the functions of the classic lone leader are distributed among all members. The tendency for one member to become automatically the coordinator of the team may not be entirely negative in the early stages of team development, but teams function most effectively when leadership roles are dispersed. Such roles include the praiser, who administers positive feedback; the harmonizer, who reduces tension with humor and nonjudgmental explanations; the conflict resolver, who identifies emerging conflicts and signals the group to begin to resolve conflict; the equalizer, who regulates flow of discussion to make sure all members have a chance to participate; the parity checker, who makes sure work loads are evenly distributed among members; the "but" watcher, who monitors discussion that blocks creative ideas by using such as language as, "yes, but . . ."; and the jargon buster, who signals when members are using specialized terms that may not be understood by all members of the group (Thousand & Villa, 1992; Zins, Curtis, Graden, & Ponti, 1988). These roles may rotate from meeting to meeting. Distributing leadership roles lets each team member know that each is valued equally and everyone on the team has valuable and unique expertise. Even the important elements, developing agenda and setting goals, are reached by team consensus. Such a leadership system also confirms that all team members are "in this together." If building administrators also join the team, they need to share leadership rather than maintain a traditional hierarchical style of leadership. Hierarchical relationships discourage creativity and consensus building among team members.

For teams to work effectively they must meet face-to-face frequently and regularly to encourage camaraderie and team work. Team functions such as goal setting and agenda development are managed more easily when groups meet frequently. Teams that meet irregularly tend to focus on too many items at each meeting or on the crisis of the week. Regular meetings give the group sufficient time and energy to address a few important agenda items per meeting. Sixty minutes is the maximum time for effective meetings; beyond that the attention and productivity of the participants decrease rapidly. Further, a proactive approach to addressing problems often results from regular meetings. However, teams trying to meet frequently face the problems of conflicting schedules and individuals who tend to arrive late or depart early. Setting strict time limits for the beginning and ending of meetings is often helpful. If the team has the support of building administrators, perhaps teachers can be released from classes, having substitutes or volunteers take over during the regular team meeting periods. Team members may agree on group norms to help reduce attendance problems: "All meetings will start and end exactly on time"; "Meetings will not be interrupted to update late members"; and "No other activities will preempt meeting times."

A second problem is that teams often are too large: Teams of 15 to 20 educators are common. Large teams find it difficult to reach consensus, have all members participate, schedule times, communicate effectively, and make members accountable. A core team of four to seven members is most efficient. While two heads may be better than one, 20 heads are not necessarily better than four. A smaller team has enough members to present a variety of viewpoints and expertise, yet also allows each member to provide a unique and valued perspective. In addition, relationships among team members grows best when the team is small. Teams can be expanded temporarily to include physical therapists, physicians, translators, educational specialists, parents, peer advocates, or students as needed for input on a specific problem, but four to seven should be the core team size. The core team should be comprised of people who are most immediately and directly involved with a specific student, and the following questions should be asked when deciding who should be on the core team: Who is most expert in the area? Who will be most affected by the team's decisions? Who will be implementing the team's interventions? Who is an effective collaborator? In addition, to keep the teams small, members may represent a larger group. For example, a team may be made up of a teacher representative, a special education teacher representative, an administrator, a parent representative, a school counselor, and a school psychologist. Representatives should solicit ideas from their constituents and inform them of the activities of the last meeting. Because school psychologists' expertise includes communication, leadership, assessment, intervention, and preventative mental health strategies, we recommend that school psychologists serve on the core team in their buildings.

Whether a group of educators becomes a creative, effective team or a resentful, dysfunctional group depends on how well they address process issues. Time and energy must be spent on group functioning and on developing methods of increasing team efficiency. The authors have observed some teams investing time in processing during the initial stages of team development, but that time wanes as the work load becomes greater. This approach is penny-wise and pound-foolish. Content is obviously important, but it is worthwhile to spend 10 minutes of every hour-long meeting on comments concerning team member satisfaction, ideas for making the team run with increased efficiency, methods of opening communication, and other process components. The payoff will be an effective, creative, and satisfied team.

An important first step in becoming an effective team is for members to state their goals for the team and their individual goals as honestly as possible. To create trust, members should accept and support other members' goals. Individual goals might be "I need to get out of my classroom for an hour"; "I like to talk with adults for a change"; "I need to feel that I have a voice in some of the decisions at this school." All are acceptable reasons for being a part of a team. Honest goals that are accepted will help make openness, acceptance, and sharing part of the team norms. The norms of trust and trustworthiness will reduce the likelihood that members will have hidden agendas.

A frequent problem is that few educators have been trained to function on an egalitarian team. Many professionals are fixed in their roles by training and are uncomfortable with others impinging on their turf. Discomfort is not necessarily bad. However, strict role differentiation is unlikely in an effective team. Although team members will have various areas of expertise, some professional overlap is to be expected and encouraged. If openness to professional overlap is encouraged and agreed upon as a group norm, then a variety of problems can be addressed at team meetings. Teachers may help school psychologists to create more relevant and realistic academic interventions based upon identified learning strengths and weaknesses. School psychologists may help teachers to individualize curriculum for students with special needs. Principals may help counselors with efficient administration of services. Relying on the unique and varied expertise of team members by sharing knowledge through open communication produces creative, effective problem solving.

Perhaps the most important process variable is conflict management. In a climate of trust and open communication conflict is inevitable. If appropriately addressed, conflict leads to creative and useful solutions to problems. However, many conflicts arise from past interpersonal problems or current power struggles. Such conflicts must be resolved as soon as they occur. Thousand and Villa (1992) present four approaches to diminish conflict in team meetings.

1. Dysfunctional behaviors that occur infrequently or in isolated situations should be ignored.
2. Humor might be used to call attention to the behavior.
3. Attention may be called to these behaviors by noting the alternative or more appropriate behaviors of other team members. For example, if a team member frequently interrupts, other team members who wait their turn or build on the ideas of others are identified for the team.
4. If the team member's behavior becomes frequent and distracting, direct confrontation should be used. Comments regarding these distracting behaviors are uncomfortable for both the giver and the receiver. However, if it is believed that the feedback will be received positively, it can be given by any team member. If a negative response is anticipated, the feedback should be given in private by someone who enjoys a positive relationship with the person.

Inappropriate behaviors that violate group norms can be confronted using these five steps (Schmuck & Runkle, 1988): (a) observe the problem member's and other's responses to the behavior; (b) try to understand why the member may be persisting in the behavior; (c) describe to the member the behavior and its effect on the team, using nonjudgmental language; (d) establish rules for minimizing future disruptions; (e) turn the unfavorable behavior into a favorable one (e.g., assign an "aggressor" the role of devil's advocate for certain issues, have the "joker" open each meeting with the funny story, assign a "dominator" the role of encourager or equalizer, have the person who wanders from the topic signal whenever anyone gets off track [Corey & Corey, 1984; Thousand & Villa, 1992]).

A common observation in team meetings is that 10% of the people do 90% of the work (Rainforth, York, & Macdonald, 1992). These teams are often characterized by a lack of trust and failure to collaborate. Equity of work is essential for group trust and harmony. This is so important that we recommend that each team have a member assigned the role of parity enforcer, who would make sure that work is distributed fairly and all members have a chance to participate. Some of the dreaded roles, such as completion of paperwork and secretarial tasks, may need to be rotated each meeting. To minimize freeloading, each member should be asked to report on the progress of agreed-upon tasks from the past meeting. Thus, members are held publicly accountable for their roles and responsibilities. When work is distributed equally and each member has ownership of the groups' goals, accountability is rarely a problem.

Most educators learn collaboration while on the job, with little formal training. A wise investment would be in-service training for all administrators, teachers, parents, and other appropriate contributors to problem-solving teams. Anderlini (1983) developed an in-service program for improving team participation in MDTs. Clearly, preservice training and supervised field experience would be the best methods of training team members. For example, the University of Cincinnati requires course work and supervised fieldwork in teaming for regular and special education teachers, and other related service personnel, including school psychologists (University of Cincinnati, 1992). If collaborative problem-solving teams are to become a part of education in the twenty-first century, the new generation of educators will need formal training.

Teams need to have a systematic approach to problem solving. An effective approach to problem solving appears in the literature on behavioral consultation (Bergan & Kratochwill, 1990). The first stage, problem identification, determines the strengths and weaknesses of systems or individuals to be targeted, ascertains discrepancies between current and desired performance, sets goals, and finally, collects baseline data to verify the problem. This first stage is the most important step in problem solving. All team members must have a clear definition of the problem in order to solve it. During the problem-identification stage, the team must separate facts from opinions, focusing only on the facts that are most conducive to problem-solving. Although this stage may appear easy to accomplish, it is often the most difficult, and it demands a great deal of time.

A commonly forgotten stage is the second step, problem analysis. The goal of this stage is to identify factors that affect the development of problem solutions. Some of the issues addressed at this stage are legal consequences, administrative issues, antecedents and consequences of behaviors (e.g., prerequisite skills, environmental conditions surrounding the behavior), sequential conditions (e.g., what time of day does the behavior occur?), and how much time individuals are willing to invest in solving the particular problem.

Solutions to the problem can be generated in the third stage. Brainstorming is an effective and commonly used method of creating possible solutions. In this technique, all members are encouraged to submit ideas before the suggestions are evaluated. Members share interventions that have proven effective with children exhibiting problems similar to those of the target child.

Given a suitable number of suggestions, members discuss the strengths and weakness of each solution until they reach consensus. Important considerations are the effectiveness of the intervention based on previous experience, the ease of use and implementation, the possible negative effects on others, the intrusiveness of the intervention, and cost and time effectiveness. The person primarily responsible for its implementation must make the final choice as to which intervention to select. If this person is pleased with the intervention selected and believes that it can work, the intervention is more likely to be executed as planned (Elliott, 1988).

When a single solution or set of solutions is agreed upon, an individual or subcommittee forges the details of the solution. At this stage, members most closely involved in the problem examine exactly what tactics are to be used and make sure that the intervention is feasible. A rehearsal of the plan may even be attempted. The members should then ask, Who will implement the plan? When is the intervention to occur? Where is the intervention to occur? How will it be implemented? How and when will the outcomes be evaluated?

The solution is then implemented. Because many plans are not executed as designed, at least one member of the team must follow-up to make sure that the solution is being performed as planned.

Finally, after a suitable period of time, the solution or plan is evaluated. Members of the team compare, through data collection, the behaviors of systems or individuals with the goal established during problem identification. Often plans need to be modified or even abandoned entirely. In the latter case, the entire process may need to be repeated, starting with problem identification. When goals are reached, it is important to congratulate all team members.

Evaluating Effectiveness

Assessing a team's effectiveness demands a two-pronged approach. Providing specific feedback on team and individual performance improves both individual and collective effectiveness. Further, evaluating the productivity and effectiveness of the team's decisions yields outcome data that the team may use for improvement. The team may also wish to catalog outcome data for an external audit. Both process and outcome measures require a data-based approach to evaluating effectiveness.

Assessment of group process must take place for both individuals and team. Thousand and Villa (1992) have developed a useful self-report scale to assess individual and team functioning, which consists of four clusters of skills: trust building, communication and leadership, decision making and creative problem solving, and conflict management. Members assign a score of 1 (I/we never do) to 5 (I/we always do) for themselves and the team for each item. Members may also note two to four items that they believe they need to improve individually or as a team. Sample items are "I/we arrive at meetings on time"; "I/we do not use putdowns"; "I/we relieve tension with humor"; "I/we ask team members' opinions"; "I/we criticize ideas without criticizing people." These items focus on 47 specific competencies upon which all teams can improve. Frequent administration of this instrument can help determine group and individual improvement on certain skills, and help create process goals for the future. In addition, informal assessment of each team member's satisfaction provides information that can produce open discussion of how team functioning can be made increasingly enjoyable and productive. Such ideas can be added to Thousand and Villa's checklist for future assessment of team improvement.

Maintaining and developing effective communication and teamwork is a necessary, but not a sufficient condition for a team to be considered effective. Teams must also create effective products. From a management perspective, meetings are extraordinarily expensive in money and personnel. Thus, teams must demonstrate that they are doing more than communicating effectively. Two measures of outcome can demonstrate whether a team is effective: the number of solutions generated and the efficacy of these solutions. Expectations for the number of solutions vary depending on the purpose of the team. For example, a MDT designed to determine special education eligibility for students should be able to address more individual problems than should a team that is creating a new reading curriculum. Using the number of solutions as one accountability variable helps keep the agenda full and meetings moving at a reasonable pace. As an outcome measure, the effectiveness of each intervention is clearly more important than number of solutions generated. Six educators functioning independently would likely create more solutions than one team of six members. However, the solutions might not be as comprehensive, creative, thoughtful, or effective as team problem solving. To test effectiveness, each solution must also have a plan for collecting data to demonstrate the efficacy of the solution. Data should be collected using such approaches as curriculum-based measurement for a student's reading problems, direct observation of a student's behavior problems, or a survey of teacher satisfaction on the newly developed lunch supervision schedule, as well as number of grade retentions, number of special education referrals, pupil achievement on standardized test scores, tardiness, discipline referrals, parental satisfaction, teacher absences and requests for transfers, student grades, number of students failing, and reasons for referrals for special education. Efficacy data may be written up in a one-page report and stored in the team portfolio. In the event of an administrative accountability review, the team can provide brief reports of successes and ongoing projects. These data will demonstrate that educational teams are more than just meeting legal mandates and finding an excuse for socializing, but are an efficient use of resources for creative educational problem solving.

SUMMARY

As the population of children in the schools becomes increasingly diverse and the concept of inclusion gains favor in many school districts, the need for comprehensive, creative, and effective educational strategies grows stronger. Further, teachers, more than ever, are receiving public criticism, and may feel powerless to make any significant changes in the way their profession conducts itself. One answer to both problems is to institute collaborative problem-solving teams. These teams, made up of professionals with a variety of skills, can develop and implement a wider variety of interventions than any single individual. Also, greater empowerment and control over what happens in the classroom can be achieved by including educators and parents on these teams. However, a collected group of people who care about children and education does not constitute a collaborative team. Before they can call themselves a team, the people involved must develop common assumptions about children and learning, as well as common goals and expectations. Leadership, group norms, processes, conflict management techniques, equity in work, training, and systematic approaches to problem solving must continually be cultivated. The patience and effort demanded to turn a group into a team can have powerful rewards for school personnel, parents, and children.

ANNOTATED BIBLIOGRAPHY

Ohio Department of Education. (1989). *Intervention assistance teams*. Columbus, OH: Author.

This is a comprehensive "how to do it" booklet on developing and implementing intervention teams from initial ideas to final evaluations. It also includes detailed lists of strategies and preventative approaches to address various barriers to effective operations of teams. It is available from The Ohio Department of Education, Division of Elementary and Secondary Education, 65 Front Street, Columbus, OH 43215.

Rainforth, B., York, J., & Macdonald, C. (1992). *Collaborative teams for students with severe disabilities*. Baltimore: Paul H. Brooks.

Although this book is concerned primarily with serving severely disabled students, it contains several excellent chapters on the benefits of a collaborative relationship among parents, medical personnel, and educational personnel. Nearly all of the authors' recommendations for collaboration serve as best practices models for mildly as well as severely handicapped students.

Schmuck, R., & Runkel, P. L. (1988). *Handbook of organizational development in schools*. Prospect Heights, IL: Waveland Press.

This handbook provides a detailed treatment of processes and issues in team meetings, and may be most useful for its presentation of team building activities. These activities are effective in building team cohesion and communication.

Thousand, J. S., & Villa, R. A. (1992). Collaborative teams: A powerful tool in school restructuring. In R. A. Villa, J. S. Thousand, W. Stainback, & S. Stainback (Eds.), *Restructuring for caring and effective education* (pp. 73–108). Baltimore: Paul H. Brooks.

This comprehensive chapter addresses many issues and problems in developing a collaborative problem solving team, as well as presenting specific strategies, including self-evaluation tools for teams. The chapter also provides excellent coverage of process variables necessary to maintain productive collaborative teams.

Zins, J. E., Curtis, M. J., Graden, J. L., & Ponti, C. R. (1988). *Helping students success in the regular classroom*. San Francisco: Jossey-Bass.

This book includes a discussion of the need, important goals, benefits, and rationale for intervention assistance teams. Unique to this source is extensive coverage of intervention designs for common academic and behavioral problems in the schools. The book includes a rationale for how intervention assistance teams can be incorporated as a system of service delivery. There is also a valuable section on evaluating the effectiveness of an intervention assistance program.

Best Practices in a Problem-Solving Approach to Psychological Report Writing

James M. Surber
Knox-Warren Special Education District
Galesburg, Illinois

OVERVIEW

Report writing has traditionally been one of the least attractive aspects of a school psychologist's job responsibilities. Avoidance can be attributed to a variety of reasons, beginning with the fact that it generally occurs after the interventions are in place, after the multidisciplinary conference, after the information has been verbally communicated and demonstrated to the referring teacher, and after eligibility and placement decisions have been made. Repeating such information in writing "after the fact" then becomes a very low priority item in the school psychologist's schedule. Since most school psychologists value and emphasize direct services to children, parents, and teachers, they often delay their report writing in favor of more professionally rewarding activities such as consultation, counseling, research, and even testing. Teachers, parents, and administrators also directly communicate their desire for the school psychologist to delay report writing in favor of providing these direct services. Many school psychologists refer to report writing as an onerous burden, to be undertaken only when forced by the end of the semester or the school year. Witness the traditional picture of the school psychologist, dictaphone in hand, attempting to decipher his/her notes and recall key information about a student who was evaluated several months earlier.

Notwithstanding their limited popularity, written reports fulfill a variety of important functions in the school. They have historical significance for other professionals and other school districts by providing a longitudinal portrait of the child. Such information is particularly helpful at the time of reevaluation when the effectiveness of a program is being evaluated. The psychological report also provides written documentation and accountability when the primary purpose of conducting an evaluation is to gather information sufficient to permit the multidisciplinary team to determine whether the student is disabled and in need of special education and related services. In probably no other profession or specialty do legislative regulations have such an important effect on the information presented in a written report. The psychological report for a student must address the source of the interference in learning, the child's unique educational needs, the answers to specific referral questions, and a determination of whether the child is disabled and in need of specialized educational services. However, we must keep in mind that the report is simply a vehicle to convert the assessment data into faithfully designed and executed interventions that lead to improved student performance.

This chapter will offer school psychologists an overview of a referral question/problem-solving mode of report writing. The emphasis will be on (a) clarifying referral questions during the consultative interview; (b) tailoring assessment procedures to answer specific referral questions; (c) ensuring that low-inference procedures precede high-inference procedures; (d) integration of the information into the report as the referral questions are addressed; and finally (e) development of interventions that assist in reducing the discrepancy between teachers' expectations and the student's performance. The first section reviews some of the problems inherent in traditional assessment and subsequent reports. Second, a problem-solving framework in the form of a referral question model of report writing is then described as a best practices approach. A discussion of methods for reducing bias during the data collection and decision-making process follows; and the final section addresses the mandated triennial reevaluation.

BASIC CONSIDERATIONS

Ysseldyke (1979) suggests that many educational personnel engage in assessment for no apparent purpose and with no clearly defined outcome for their findings. This lack of direction in assessment is most evident in the use of a standard battery in the identification of disabled students. Standard batteries typically include the administration of an intelligence test, a standardized achievement battery, and a measure of visual–motor coordination. Reschly and Wilson (1990) report that school psychologists devote approximately 65% of their time to various activities related to determining special education eligibility. Typical services often reflect a refer–test–place–forget sequence in which intellectual assessment is the prominent source of data collection. However, these standardized tests are relatively useless and potentially harmful to children if their use does not emphasize interventions and recommendations for reducing the interference to the child's learning. To date, there is no empirical support for the use of standard batteries in answering specific referral questions or planning appropriate instruction for students. In fact, they miss the key referral concerns in a majority of cases.

The use of these so-called standard batteries have been criticized for a variety of reasons, ranging from fairness to students to concerns about validity of the assessment and placement decisions (Reschly & Wilson, 1990). More specifically a standardized battery makes it extremely difficult, if not impossible, to address a variety of potential referral concerns. Second, such practice does not lend itself readily to an integrated approach. Third, the traditional report often presents intellectual, educational, fine-motor, and behavioral/emotional data in a compartmentalized format with each area assigned its own heading. This format typically places the burden of determining what information is relevant on the reader, rather than the author. Finally, the last paragraph, often titled "Summary," is left for the integration of all the separate sections. Consequently, the reader typically pages ahead to the summary section without gaining the benefit of an integrated approach. Integration of the assessment data should occur throughout the report, not just in the summary (Batsche, 1983).

In response to heavy caseloads or in an attempt to provide written feedback in an expedient manner, many school psychologists feel restricted in the amount of time they can devote to the development of a report. As a result, the psychologist's report is limited to 1–$1\frac{1}{2}$ pages, addressing instruments used, test scores, and special education eligibility. This format tends to be generic, not providing the reader with a clear picture of the referred student. At the opposite end of the continuum, some of the more lengthy reports include every detail of the evaluation process, whether relevant or not. Both novice and experienced readers are left to wade through the jargon, attempting to ferret out the key elements that have relevance for the student and the teacher in the classroom. Consequently, items of greatest relevance become diluted in the sea of information being washed ashore. Tallent (1993) noted that the longer the report, the less significant any given item becomes, causing the relevance of the content to gradually fade. During the process of report writing, the school psychologist must give as much consideration to what information should be left out of the document as to what should be included.

Computer-assisted reports also have the inherent weakness of so-called information overload. Although such programs have an initial lure for time-strapped psychologists, Matarazzo (1986) reported that "With almost no exception, today's software produces only a single, typically very lengthy, clinical narrative." As anyone who has used them can attest, computer-generated reports, with their limited bank of canned phrases and interpretations, result in a "horoscope" of oversimplified conclusions.

Readability is also a source of concern when reports serve as the primary mode of communication with the referral agent. Consequently the rule of thumb is that psychological and educational jargon must always be avoided. If not, statements may not be understood, which reduces the psychologists' credibility, making the report nothing more than a source of frustration for the classroom teacher. Thus, the writer is left with the problem of reporting the assessment in such a way as to exclude common terms for explaining the meaning of the data, such as "visual-motor coordination," "verbal/performance discrepancies," and so forth (Ownby, 1987). However, this dilemma can be avoided if such terms are followed with a detailed explanation of how the identified strengths or weaknesses are manifested and demonstrated by the student in the educational setting. These explanations take on added significance if we consider survey research in which school psychologists report continuing concerns with insufficient time devoted to formulating intervention plans during multidisciplinary conferences (Huebner & Gould, 1991). Considering the limited time available at staffings to explain evaluation results and recommendations, the report may take on greater significance in detailing the interventions that were developed as a part of the assessment process. In general reports must be child-centered, objective, positive, integrated, concise, and outcome-based, and they must be completed in a timely fashion.

BEST PRACTICES

Tallent (1993) points out that the psychological report is clearly a reflection of the role that the psychologist has assumed within the school environment. If the psychologist's role is limited to that of "tester–technician," the document produced will reflect this narrow focus and will be restricted to the reporting of test results. On the other hand, if the psychologist functions as a consultant, the format of the report takes a markedly different direction. When the psychologist's role is expanded to include consultative services, the approach to assessment becomes "related to a distinctive prescription for educational practices . . . that leads to improved outcomes for students" (Heller, Holtzman, & Messick, 1982). The resulting document moves beyond the simple reporting of test scores to the development of educationally relevant interventions that can be understood by parents and put into practice by school personnel. Although many school psychology training programs are incorporating this consultative model into all aspects of training, a large number of practicing psychologists have made this transition on their own through preservice training, in-service presentations, and other self-initiated professional development activities. This transition has been fueled by the fact that most school psychologists find the model professionally rewarding because of its relevance and direct benefits to both the student and school personnel.

With this shift from assessment for classification decisions to assessment for intervention purposes (Gresham, 1983), practicing school psychologists need to examine their roles in the school to determine if their style of report writing is consistent and current with a problem-solving theoretical model. The most likely match for this current best practices approach to assessment is a problem-solving report-writing model. From examining this model, it also becomes evident that it includes many built-in safeguards that will assist the psychologist in avoiding many of the pitfalls associated with more traditional models.

Problem-Solving Report-Writing Model

The premise of the problem-solving report-writing model is that the collection of assessment data is for the purpose of developing quality interventions. As Batsche (1983) suggests, a problem-solving report-writing model responds to a variety of weaknesses inherent in traditional reports. First, it ensures that both the assessment and the report are individualized and address the specific referral questions. Second, the report is intervention-oriented and clarifies the reasons for the referral. Third, it increases the treatment validity of the assessment procedures; and finally, the report is tailored directly to the referral source.

Conceptually, a problem-solving model utilizes the selection of assessment devices that are geared to answering specific referral concerns, which in turn lead to relevant classroom interventions. However, the relevance of any intervention cannot be determined adequately in the absence of defensible levels of adherence to the intervention plan and of treatment integrity (Gresham, 1991). Meichenbaum and Turk (1987) define intervention adherence as the degree to which the classroom teacher is committed to implementing a specific intervention and actively demonstrates behaviors directed toward this end. Treatment integrity, a term closely related to intervention adherence, describes the degree to which an intervention is planned and implemented in good faith (Gresham, 1989). Zins and Ponti (1990) point out that these two variables are clearly the critical issue in producing successful outcomes for students in a problem-solving model (see Telzrow in this volume for more information regarding intervention adherence).

Failure of such documented interventions would then be the basis for initiating the case study evaluation process. If the child does not respond to the interventions at his/her instructional level in curricular areas, the probability increases that a learning or behavioral deficit exists. The results of these interventions should be used as the basis for making decisions regarding further educational recommendations and/or establishing the need for initiating a referral. To ensure treatment integrity, it is recommended that there be documented evidence of at least three attempted interventions in the regular classroom. Such a procedure is critical to ensure appropriate referrals and to rule out academic or behavioral problems that are not the result of a disability. Resistance to training may be a better indicator of a disability than present levels of performance that have been generated by a battery of standardized tests. Since there are many reasons for learning and behavior problems in the school environment, it is essential to have a plan for studying children systematically before referring them for comprehensive case study evaluations. Such a model emphasizes a preventative approach with modified instruction to assist children who are experiencing difficulty. This process takes advantage of existing professional skills and helps to eliminate problems that may be related to factors other than disability. This procedure is consistent with the concept of least restrictive environment and may help reduce the number of children who are too quickly referred, evaluated, classified as disabled, and placed in a special education program. Such a procedure should not be used or misinterpreted as an approach for delaying the provision of services to disabled children. In fact, the purpose of such preliminary data collection is to expand available assistance to students in the regular classroom, not to deny needed services (Zins, Graden, & Ponti, 1988).

The generic problem-solving model described in this chapter should be thought of as a continuum that begins with preliminary data collection in the regular classroom that may or may not lead to a case study evaluation. The following are recommended steps in the process:

Steps in the Problem-Solving Model

Request for services. When a student's academic and adjustment problems are a persistent concern, the classroom teacher should submit a request for assistance to the school psychologist, building-based team, and so on. Parents are always informed of the associated concerns and encouraged to be active participants in the process.

Preliminary data collection. Following receipt of a request for services, the first step is to review and/or collect available information regarding the student. This may involve a review of records, test scores, grades, discipline reports, work samples, primary mode of communication, language proficiency data, information from parent conferences, classroom observations, and any other relevant information. This data will ensure that the school psychologist and the building team are informed partners during the consultative interview.

Consultative interview. The development of appropriate interventions begins with a consultative interview with the referral source. The goal of the interview is to strategize the problem-solving process by focusing on prior interventions, desired outcomes, student's strengths and a definition of the referral concerns in a behavioral theory-specific and discrete form. This process is metacognitive in that it allows the participants to think about their own thinking. Teachers are given time to think about what they know, what they do not know, and what they need to know about solving the problem (DeBoer & Ciello, 1990). Listed below are recommended points that should be addressed during the interview. The areas do not necessarily need to be reviewed in the order in which they are presented. Rather they should be answered at naturally occurring times during the consultative interview.

1. *Problem statement:* The interview will begin with a general statement/overview of the concerns expressed by the referral agent.

2. *Problem analysis:* In this step the referral questions are behaviorally defined. Typically the majority of the interview is spent on clearly identifying the problem. This follows from the thesis that the best interventions are more obvious and acceptable to teachers once the problem is clarified and framed.

3. *Prior interventions:* The teacher will discuss the success or lack of success of interventions that have already been attempted in the classroom. This may serve as the basis on which to build subsequent solutions.

4. *Desired outcomes:* Here it is important to have the teacher identify the desired replacement behaviors. In other words what they would like the student to be doing that she or he is currently not doing.

5. *Student's strengths:* This step actually serves two purposes. First, it requires the participants to focus on the student's assets in addition to the deficit areas. Second, interventions can be centered around the child's strengths. This strategy assists in movement away from a deficit-oriented model and builds on existing skills and abilities.

6. *Interventions to be implemented:* In collaboration with other team members, the school psychologist should not have preconceived notions of how to solve the problem. Solutions tend to evolve as the problem is clarified. No suggestions should be offered by the consultant(s) until the referral agent has explored all of his or her own ideas, resources, and possible options. Offering possible solutions too early in the process is a guarantee of failure. Until teachers have ownership of the problems they report, they are not likely to focus all of their energy on solving them. Interventions must be predicated on teaching new behaviors not just reducing or eliminating undesirable behaviors. If the intervention does not involve a teachable skill, it will not be an effective intervention.

7. *Monitoring system:* Before the interview is brought to a close, there must be some agreed-upon method of monitoring the student's progress. For example, nonobtrusive documentation may take the following forms: percentage of work completed; percentage of time in seat; comparison of work samples; event recording; time sampling; percentage of correct work; and so forth.

8. *Follow-up date:* A follow-up date should always be set. This provides for a specified amount of time to evaluate the effectiveness of the interventions.

Development of Referral Questions

As early as 1967 Rucker reported on the results of teachers' ratings and the usefulness of reports written by experienced and by less experienced school psychologists. Although the results were statistically nonsignificant, the teachers completing the ratings judged that the most useful reports were those that clearly answered the referral questions (Ownby, 1987). Consequently, the key element of defining the referral concern behaviorally provides not only the rationale for data collection, but also the means by which the school psychologist can successfully link assessment data to clearly defined interventions.

Best practice requires that referral questions be limited to those that are definable, measurable, and relevant to the educational concerns of the child, and that are agreed-upon and prioritized. The continued use of standard batteries can be attributed in part to the lack of clearly defined referral questions. Questions that lend themselves only to classification concerns are inappropriate and not considered relevant for the development of classroom interventions. The referral question is generated during Step 2 of the interview process. Other questions can be added at the discretion of the school psychologist, after limited success with the interventions or when it is decided to go to a case study evaluation. The questions should be listed individually throughout the report with the source of the question identified. Examples: (a) Why is it difficult for Richard to complete his independent seatwork successfully? (Ms. Schmidt, classroom teacher); (b) How good are Sarah's reading fluency and comprehension skills compared with her current grade placement and measured intelligence? (Ms. Jones, Chapter 1 reading teacher); (c) Why is Mike noncompliant during direct instruction; what precipitates the inappropriate behavior and what maintains the behavior? (Mr. Hall, second-grade teacher); (d) Are Johnny's poor attending skills interfering with his academic performance? If so, how can his productivity in the classroom be increased? (Ms. Becker, fifth-grade teacher).

Selection of Assessment Procedures

When choosing assessment procedures, it is important to keep in mind that the selection of each procedure must be purposeful in seeking an answer to a referral question, not merely serve as an essential element of a standard battery or so-called multifactored assessment.

There are primarily five types of data that may be utilized by school psychologists in answering referral questions and formulating educational interventions:

1. Reviews of available information.

2. Interviews with significant persons who have direct contact with the child.

3. Observations, both anecdotal and standardized.

4. Testing, which may include norm-referenced, criterion-referenced, and/or curriculum-based measurement.

5. Vision and hearing screening.

Review of available information. Both temporary and permanent records paint a very good picture of a child's educational history. This information can be extremely useful in determining if present levels of performance are consistent with reported and observed behavior in the current school environment. If the current behavior is divergent from the child's previous behavior, it may indicate a situational or instructional variable (e.g., a recent traumatic event or a conflict with an individual teacher or subject area) rather than an established pattern of performance over time.

Interviewing. Interviewing persons who have direct contact with the student is extremely important in gaining an understanding of the child from the people that know her or him the best. As outlined in the section above, interview information is extremely important, even vital in determining present patterns of behavior, gaps in learning, effective reinforcers, effective consequences, and the basis for hypothesis testing of unknown information.

Observations. Sattler (1988) suggests that behaviors recorded over a sufficient period of time will reflect a representative sample of the behaviors under observation in the school. Observational data, both anecdotal and standardized, are an important source of information to be considered prior to the consultative interview and before the development of interventions. Such information is objective, reliable, verifiable, clear, and complete and can serve as a direct link between the formal test data and the actual classroom behavior. It is also helpful in quantifying behavioral characteristics and establishing a baseline for the development of interventions.

Testing. *Testing* is often used interchangeably with the term *assessment*. However, testing is only one component that falls under the umbrella of assessment. Testing can be formal in the case of norm-referenced tests, which are used primarily in the classification of disability areas. Criterion-referenced testing, on the other hand, is used in the determination of instructional levels and the development of educational interventions.

Vision and hearing screening. Although listed last, this information may be the most important because it rules out any sensory impairment that may be contributing to the difficulties a student is experiencing in the classroom. It is extremely important that a sensory deficit not be incorrectly interpreted as a skill deficit in an academic subject area.

Selection of Assessment Devices

After the school psychologist has developed specific referral questions, the assessment devices must be selected and tailored to answer the specific questions. These assessment techniques are not rank-ordered and no single method should be considered more important than another. Rather, the choice will vary depending on the referral question and the desired information. For example, it is not necessary that every child referred for a case study evaluation be routinely administered a standardized intelligence test. If a child is acting out in the classroom despite a demonstration of above-average academic and abstract reasoning skills, an intelligence test is clearly not warranted. In this case, the most relevant information may be standardized observations, behavior rating scales, and interviews with the parents and teacher. These data collection methods have a much better chance of answering the referral concern, which in turn leads to relevant interventions.

Sequence of Assessment

An important step in minimizing outcome bias is making sure that the assessment sequence proceeds from low-inference to high-inference items. Low-inference methods are objective and require a minimum of subjective judgment or psychological interpretation to reach consensus. Such data collection methods include observation, review of records, interviews, student work samples, and so on, which will ultimately influence the selection, administration, and interpretation of high-inference procedures. The collection of these objective data should lead to the development of hypotheses for developing predictions that can and should be tested through the collection of high-inference procedures. It is through the development of relevant, predictive, and testable hypotheses that the school psychologist moves beyond merely accumulating and reporting facts into an evaluation of the linkages among the facts. For example, the teacher may express a concern about the poor quality of a student's independent seatwork. The school psychologist might immediately question whether the student has the necessary reading skills to complete the work. If the teacher is unsure, this could be checked out by suggesting that he or she establish an instructional level through the use of curriculum-based measurement. Skills deficits in other areas and slow rates of learning may suggest the need to move to data collection procedures that require a higher degree of inference, such as cognitive batteries or intelligence tests. These methods are obviously much more hypothetical and require higher degrees of subjective interpretations to confirm or deny the predictions about the student. The point is that if the high-inference procedures are conducted first (as often is the case), conclusions may be incorrectly drawn about the student that are not consistent and convergent with the student's performance in the classroom. When such methods are put into practice, biased outcomes for students often result. To minimize this as a source of bias, it is recommended that assessment proceed in the following manner: review of records; vision and hearing screening; determination of language dominance; classroom observation(s); interview with teacher; interview with the parents; review of work samples; determination of educational achievement through the curriculum; completion of behavior checklists; and assessment of adaptive behavior, achievement, intelligence, learning processes, and personality.

Answering Specific Referral Questions and Converging Multifactored Assessment Information

The answers to specific referral questions must begin with an analysis and integration of the diverse sources of information. As Gresham (1983) suggests, the most meaningful way to integrate evaluation information is through the use of a multitrait–multimethod approach. Such an approach utilizes numerous methods (tests, interviews, observations, reviews, etc.) to assess multiple traits (intelligence, adaptive behavior, academic achievement, etc.), in order to determine the consistency of the results across methods and traits. This requires the school psychologist to shift assessment efforts away from a simple description of the results to an integration of the data that requires a high level of agreement between and within assessment methods. When convergence of the results exists and all the data are pointing toward the same conclusions, the school psychologist and other team members can feel much more confident about the answers to the referral questions and subsequent recommendations. If there is a lack of agreement between or within these methods of assessment, then further investigation of the referral questions is mandatory. For example, if the results obtained from the standardized tests are not consistent with the teacher's reports, parents' reports, work samples, and classroom performance, then additional investigation is needed to determine the reasons for the divergence of the information. In such a case there may be several reasons for the lack of consistency between data sources. First, the standardized procedures may be invalid and not constitute a true representation of the student's ability. Second, the variation in scores may be due to the different response patterns in a group versus an individual setting. Or the differences may represent the lack of curriculum validity between what is being taught and what is being tested by the norm-referenced tests. Regardless of the reasons, additional referral questions must be generated and answered before one proceeds with further analysis, integration, classification, recommendations, or interventions. Without such careful scrutiny children will continue to be inappropriately labeled and placed in special programs without a clear understanding of the reasons for the interference in learning, the necessary interventions to reduce the interference, and the best educational setting for implementing the recommendations. It is important to remember that placement of a child in special education is not an intervention; it is merely a change in location. There must be clearly defined reasons for the placement and evidence that the interventions can be accomplished only in a setting outside of the regular classroom.

RECOMMENDATIONS/INTERVENTIONS

Recommendations for the development of school-based interventions that are directly linked to the referral concerns will conclude the formal process. While this framework relates to observable aspects of the student's behavior, it does not imply that the only treatments that are appropriate are behavioral. The treatment technologies may be as varied as the ingenuity of the people involved in designing interventions. When interventions are agreed-on and definitively chosen, the rule of thumb is to "think big and begin small." In other words, easy-to-implement solutions are preferable to grandiose interventions that may be disruptive to the classroom, time-consuming, and difficult for the teacher to monitor. It is also important that recommended interventions be developed in such a manner that they can be implemented with a minimum of guidance from the school psychologist or other team members. New interventions should be built on existing structures, or ideas previously implemented by the teacher, that may have been abandoned too early. Always plan for maintenance and generalization of skills and get students involved in monitoring their own progress. Each recommendation should be taught and/or demonstrated to the teacher in the classroom if it is an unfamiliar technique. The effectiveness of interventions should be data based rather than subjectively determined by teacher observation.

REEVALUATIONS

Reports of reevaluations will be approached from the perspective of determining individual education plan (IEP) relevance, measured progress of goals and objectives, appropriateness of setting, and needed interventions or changes. From a legal perspective, the reevaluation process must address all components of the initial or most recent regulatorily complete case study evaluation. The nature and thoroughness of each component will vary depending on the individual needs of the student and the pertinent information already available in the student's educational record. It is reasonable to expect that certain types of information may not change significantly during the time period between the most recent case study evaluation and the reevaluation. The evaluation team must demonstrate professional judgment regarding the amount and type of evaluation to be performed based on available information. Under certain circumstances a reevaluation need only be a review of records and current progress with appropriate recommendations. On the other hand, circumstances may indicate the need for a complete assessment of all case study components.

Best practices would suggest that the student be reevaluated by utilizing the four following problem-solving steps.

Review of All Existing Data Available on the Student

This should include a review of the child's permanent and temporary school records and any pertinent information (work samples, test results, etc.) collected by the classroom teacher(s). In evaluating the child's confidential file, particular note should be made of the IEPs for the last 3 years. The IEPs should be reviewed to determine to what extent the student has met the goals over the past 3 years.

Interview with the Child, Parent(s), and Teacher to Develop New Referral Questions

The purpose of the interview is to gain information about the student, to clarify what additional information is desired by the parent and/or teacher(s), and to develop definable and measurable referral questions.

Selection of Appropriate Assessment Procedures for the Referral Questions

There are basically four methods of collecting data for assessment purposes: observation, reviewing, interviewing, and testing. The method of choice will be determined by the individual needs of the student and the pertinent information already available.

Selection of Intervention Strategies

Recommendations and interventions should be organized from the information that was gathered during the interview process. Once sufficient information in the form of specific referral questions has been gathered, the school psychologist must select assessment procedures designed to answer those questions. This will help to ensure meaningful outcomes for the student.

The primary intent of the reevaluation is to ensure that the continuing individual needs of the student are identified and that the relevant information for present and future programming is available. As the student progresses through his or her specific program, referral questions will continually be generated, information gathered, and interventions implemented.

SUMMARY

In brief, psychological reports are a reflection of how the school psychologist practices. If the majority of time is spent testing children and determining eligibility for special education, the report will convey such an approach. In turn, if the school psychologist operates within a consultative, problem-solving, referral question model, the written results, recommendations, interventions, and ultimate outcomes for the student will be graphically represented in the psychological report. Consequently, a review of best practices in report writing must be preceded by a discussion of best practices in the delivery of services. It is the intent of this chapter to demonstrate how report writing and practice are inextricably intertwined.

Psychological reports must continue to evolve by moving beyond the simple reporting of individual test scores and determinations of eligibility for special education. It is important to keep in mind that placement of a child in a special education program is not an intervention; rather special education is a setting in which appropriate services may or may not be delivered. The environment in which these services can best be delivered depends on the needs of the individual student. We have all heard of special education referred to as a "deficit model" and the psychological report as a search for the pathology. Consequently, it is vitally important to avoid the reporting of assessment data that emphasize only deficits and negative aspects of the child. The positive aspects of the child must be emphasized as well, with the building of interventions on strengths, rather than weaknesses. In order to do this, reports must be more than a review of scores generated from a standard battery of tests. Such an approach incorrectly encourages a shotgun approach in which an effort is made to report every conceivable characteristic of the child. This produces a document that is poorly integrated and focuses on test results rather than the student's needs. It is common in this type of report to interpret each test individually with limited attention to how the results from one area may affect the outcomes in other areas. Reports written in this style tend to be a very broad review of nonspecific and irrelevant information (Tallent, 1993). Rather, the mission of the psychological report should be a review of answers to referral questions that lead to faithfully executed interventions that assist in reducing the interference in learning.

The appropriateness of interventions is contingent upon the collaborative problem-solving team's having a thorough understanding of the student's needs. The standard of excellence in a problem-solving approach is whether the referral question has been behaviorally defined and is consistent with recommended interventions and desired outcomes. The linking of assessment to intervention continues to be one of the most complex and challenging demands placed upon today's school psychologist. However, it is important that this link be established and the challenge be met in order for the student to be the beneficiary of appropriate school-based interventions.

Psychological reports represent one of the key components of a case study evaluation. Although reports are often criticized for their jargon and lack of relevance for classroom interventions, the psychological report remains an important communication link between the psychologist and regular and special education teachers, parents, administrators, community agencies, pupil personnel staff, and all other staff involved with the student.

In a practical sense, it is important that the report be clear, concise, meaningful, integrated, and well-organized. It is imperative that the turn-around time for reports be short in order for them to be a useful tool for the school personnel engaged with the student on a daily basis. Teachers are pleased to receive shorter, more timely, reports that will assist them immediately with their intervention efforts.

The model outlined in this chapter defines assessment as a problem-solving process with a focus on the reasons for assessment and outcome-based interventions. The identified problem(s) cannot be solved and the team cannot collaboratively contribute to the solution until questions and referral concerns relevant to the child's educational problems are behaviorally formulated, specifically defined, in measurable terms, and agreed upon by all participants. Clearly defining the referral concern provides the only rationale for any assessment or data collection by the school psychologist. The report evolves naturally as a part of this consultative process by addressing relevant background information, giving specific answers to referral questions, describing the interference in learning, and tailoring interventions to answer the specific concerns. Such an orientation precludes the school psychologist's role as the administrator of standard batteries and recognizes that not all school-based concerns are dealt with in the same manner. By attending to the sequence of assessment and incorporating a multimethod, multitrait approach, the school psychologist can better ensure that the outcomes for students are nondiscriminatory.

It is hoped that this chapter will assist school psychologists in understanding the importance and value of providing integrated, data-based reports that respond to identified concerns and lead to positive outcomes for students, teachers, and parents.

ANNOTATED BIBLIOGRAPHY

Grimes, J. (Ed.). *Communicating psychological information in writing.* Des Moines, IA: Iowa Department of Public Instruction.

This resource guide describes approaches and considerations involved in school psychologists' communication of information in reports. Following an initial tongue-in-cheek discussion of principles of report writing by J. Grimes and G. Ross-Reynolds, the same writers focus on "Three Counter Proposals to the Traditional Psychological Report," in which revised formats of the same report are presented. G. Batsche describes the "Referral-Oriented Consultative Assessment Report Writing Model" and F. Gresham reviews the multitrait- -multimethod approach to test validation and applies the approach to psychoeducational assessment and decision making. In the final chapter Ross-Reynolds reviews the "Three-Year Reevaltion: An Alternative to the Reevaluation–Means–Retest Model."

Ownby, R. L. (1987). *Psychological reports: A guide to report writing in professional psychology.* Brandon, VT: Clinical Psychology Publishing Co.

This book does a very good job of addressing the difficulty of translating assessment results into writing. Ownby does this by developing a theory-based outline of report-writing practices and a structure for considering the problems associated with report writing. This resource has a strong clinical orientation with the exception of a brief section in Chapter 7. However, this would still be an excellent resource for the experienced practitioner desiring a refresher and a must for the school psychologist in training.

Ross-Reynolds, G. (1990). Best practices in report writing. In A. Thomas & J. Grimes (Eds.), *Best practices in school psychology–II.* Washington, DC: National Association of School Psychologists.

Ross-Reynolds does an excellent job of reviewing a variety of alternative report-writing models from which psychologists may choose to make their reports more effective. The models reviewed include the traditional report; psychological reports—revised format; letter and memo formats; referral-oriented, consultative assessment reports; translated reports; graphs in reports; and computer-assisted reports. The chapter also includes a self-assessment checklist that serves as an excellent self-monitoring device for the school psychologist with all levels of training and experience. Any psychologist writing reports on a regular basis should periodically review this chapter.

Sattler, J. M. (1988). *Assessment of children* (3rd ed.). San Diego: Jerome M. Sattler, publisher.

Sattler provides an essential reference as well as an excellent text for all professionals involved in the assessment of children and the writing of reports. Several examples of both correct and incorrect report-writing models are provided as learning tools. The pitfalls common to psychological reports are reviewed and an outline for a best practices approach to report writing is recommended. This book is a requirement for all professional libraries.

Tallent, N. (1993). *Psychological report writing* (4th ed.). Englewood Cliffs, NJ: Prentice-Hall.

In his fourth edition Tallent does a masterful job of providing an overview of all aspects of psychological report writing. Although greater emphasis is given to clinical report writing, Chapter 10 is devoted to psychological report writing in the school setting and provides a great deal of insight into the difficulties encountered in schools. This is an excellent reference for school psychologists.

Best Practices in Training School Psychologists

Karen T. Carey
Marilyn S. Wilson
California State University, Fresno

OVERVIEW

This chapter is intended for school psychology students, practitioners, and trainers. Changes in the field are forced by shifts in the constituency (students and schools) and facilitated by ongoing research on learning and behavior. Ongoing evaluation of school psychologists' personal skills and training programs are needed to evaluate congruence with the history of school psychology, current roles, and challenges of the future. A brief history of school psychology training is presented first in this chapter, followed by information on skills needed for the 21st century. Training standards promulgated by the National Association of School Psychologists (NASP) and the American Psychological Association (APA) are reviewed and questions related to training that require reflection and resolution are raised. Future directions for training in school psychology are then presented.

Early Training in School Psychology

Psychological, educational, and relevant medical services to assist school-age children in making academic progress have been provided on varying levels for nearly 100 years. In 1896, Lightner Witmer founded the first psychological clinic at the University of Pennsylvania. Others soon followed Witmer's lead and clinics were established in Chicago, Detroit, and other cities. As time went on, school psychologists were employed by school districts and began to travel to schools in order to provide services to students (Fagan, 1986; French, 1990).

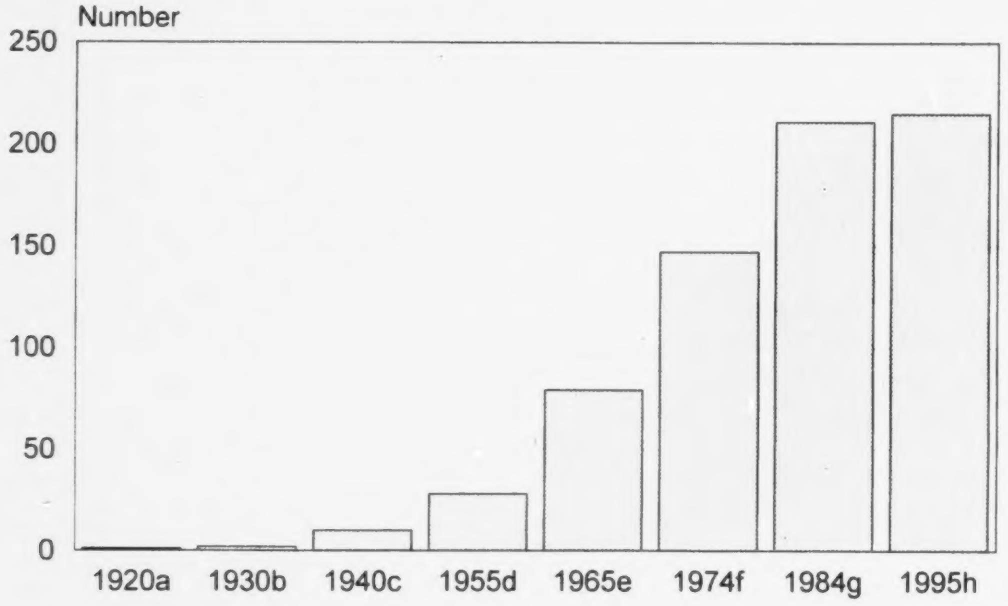
During the period 1900 to 1940 the majority of these early school psychologists obtained applied training in university clinics. In the mid-1920s New York University started the first training program. Training programs and courses were soon developed at other universities in New York as well as at universities in Pennsylvania and Ohio in the 1930s. By 1940, 500 school psychologists were providing services to students (Fagan & Wise, 1994). In many states training in school psychology was initially provided through credentialing programs in adjunct fields (e.g., special education, counseling). By 1970 more than 100 universities were training school psychologists, and 40 states were credentialing school psychologists. The 1975 passage of Public Law 94-142, the Education for All Handicapped Children Act, provided the impetus for tremendous growth in training programs explicitly in school psychology, from approximately 33 programs in 1964 to 230 training programs today (Fagan & Wise, 1994; see Figure 1; also see Appendix IX).

Development of Training Standards

The issues of accreditation of programs and entry level for practitioners have been debated from the beginning days of the field. In the early 1970s, school psychology programs gained some recognition from the National Council for the Accreditation of Teacher Education (NCATE); however, the training standards developed by NASP in 1972 were not enforced in a strict and structured manner. NASP was established as an affiliate of NCATE in 1976 and in 1978 the NASP standards for school psychology training were revised. In 1978 NASP recommended that school psychology students complete a 60-hour program and a 1-year internship as minimum level of entry. As an affiliate of NCATE, NASP now approves programs and program accreditation is granted by NCATE (Brown, 1990). APA has traditionally supported only doctoral-level psychology, and in 1969 APA developed standards for accrediting doctoral programs in school psychology. The first programs were evaluated and accredited in 1971. There are currently 44 APA-approved school psychology programs and 5 joint (e.g., school, clinical, counseling) APA-approved programs (APA, 1993, 1994).

A joint APA/NASP Task Force was formed in 1978 to resolve areas of overlap and conflict in NASP and APA training and professional standards. The Spring Hill Symposium, held in 1980, was an attempt by NASP and APA to partition responsibilities for doc-

FIGURE 1. Number of school psychology programs by decade.



aNYU; bNYU & PA State U; cFarber, 1956; dCutts, 1955; eSmith,1964-65; f Bardon & Wenger, 1974; gBrown & Minke, 1984; hSmith, 1995

toral and nondoctoral training (Trachtman, 1981). Multiple models of training were endorsed: entry-level nondoctoral (specialist) programs, practitioner-focused doctoral (PsyD) training, and traditional doctoral (PhD) training. The ongoing issue of specialization-versus-a-generalist model of training was also considered, resulting in support for the generalist model.

Training continues at the nondoctoral and doctoral levels, with nondoctoral programs continuing to train the majority of school-based practitioners. A doctoral program requires one to two years additional academic coursework plus dissertation or major project, written and oral exams, and a 1500-hour internship. The opportunity to develop a specialization is frequently a motivation for pursuing doctoral studies. However, documentation of actual program content reveals that much of the actual coursework may involve research and design rather than an area of specialization (McMaster, Reschly, & Peters, 1989). Therefore, the role of, and training for, doctoral-level school psychologists continues to be debated. Students should choose doctoral programs that are congruent with career goals (e.g., school practitioners, academic, or private practice).

Conferences have played an important role in guiding psychology training. In 1949, the Boulder conference on clinical psychology was held in Boulder, Colorado. Although this conference was not specific to school psychology, issues related to training and credentialing were discussed. The outcome of the conference was to recommend that all students in applied psychology be trained as scientist-practitioners. The Thayer conference, held in 1954, was sponsored by APA. Resulting recommendations for school psychology training included a 2-year program and a 6-month internship at the subdoctoral level with a 4-year program recommended for the doctoral degree.

Two major conferences related to the training of doctoral-level psychologists were subsequently sponsored by APA. At the 1987 Utah conference, resolutions on the requirements of the structure and core-curriculum content for undergraduate through post-graduate training in psychology were developed (Lambert, 1993). In 1990, the Gainesville Conference on the Education and Training of Scientist-Practitioner Psychologists for the Professional Practice of Psychology was held. This conference resulted in recommendations for identifying and training scientist-practitioners. Future conferences related to training and practice are in the planning stages at the time of this writing and focuses include the means by which training programs can meet all areas of current training standards, the development of future training standards, and the evolving roles of women in the field.

Another endeavor to maintain high standards for programs and individual practitioners was the establishment of standards for the National Certification of School Psychologists (NCSP) developed by NASP in 1985 (Batsche, Knoff, & Peterson, 1991). Goals of the NCSP included national recognition of professional development and reciprocity between states. Thus, a student trained in Minnesota who was NCSP certified could relocate to Arizona without the need to complete additional coursework. In 1988–89 school psychologists currently practicing in the field took a national examination in order for cut-off scores to be determined. Anyone taking the exam could then apply for NCSP status through grandparenting regardless of the score obtained. Cut-off scores are revised regularly. Students completing NASP-approved programs may now apply to take the certification exam and, upon passing the exam, receive the NCSP.

The NASP standards for training and field placement in school psychology were revised in 1984 and the National School psychology Inservice Training Network published *School Psychology: Blueprint for Training and Practice*. School psychology was envisioned as a broad field encompassing roles in educational, intellectual, and interpersonal assessment and consultation; in academic skills, instruction, and classroom management; in home–school–community relations in an increasingly multicultural context; and in legal, ethical, and professional issues relevant to schools, students, and the profession. Phillips (1990) also advocated new roles for school psychologists. His vision was oriented toward doctoral-level school psychologists with specialization in behavior and learning. Others (Epstein, 1992; Woody, LaVoie, & Epps, 1992) have recently visualized school psychologists of the future as psychologists serving the mental health needs of entire school populations, students, and their families. The scope of these predictions is exciting but overwhelming for the currently already rigorous school psychology training program.

Training School Psychologists for the 21st Century

The populations of America's schools are becoming more multifarious. School psychologists are increasingly assisting teachers and parents of children with severe disabilities and medical problems to determine and construct least restrictive environments. As special education legislation expands and emphasizes services to youngsters with disabilities from infancy to young adulthood, a concomitant need exists to augment skills in areas such as assessment of young children and their families and to delineate transition programs. Many children are coming to school from poverty or diverse cultures. School psychologists are involved in planning and implementing classroom and home–school interventions to support children, families, and teachers. More practitioners are finding it imperative to determine how best to assess children whose backgrounds do not match most standardization samples and to advise schools on how and where (regular or special education) to provide appropriate educational services. As practitioner roles expand, so should training. Planners and educators cannot anticipate all the skills psychologists of the 21st century will need but must provide students with a strong foundation in psychological and educational principles, knowing that will not be sufficient. A focus of graduate school should be to provide students with critical thinking and evaluation skills. As formative evaluations and problem solving become ever more critical to the practice of school psychology, so should they be stressed in training.

Historically, training programs have both led the charge to aid children with learning and behavior problems and reflected specific practices deemed fitting by legislation. However, Curtis and Batsche (1991) ask whether school psychology training programs are leading the field or following it. Training programs operate within the constraints of accreditation and credentialing systems and the pragmatic pressures of graduating students who met the needs of the job market. School psychology programs struggle to maintain quality training in assessment courses and expand the content of assessment to include areas such as bilingualism and preschool materials, while increasing emphasis on intervention and consultation coursework (McMaster et al., 1989). Program faculty can direct students to resources and insist on excellence in knowledge of test construction, statistics, and legal and ethical issues in order that students have the skills to evaluate the adequacy of new and future technologies.

The array of student populations and needs today mandates recruitment into the field of school psychology of persons from various backgrounds and ethnic groups and persons with disabilities and greater balance in gender and race within training programs. School psychology practitioners currently in the field are very unbalanced ethnically (approximately 92% are Caucasian) and increasingly lopsided in gender (70% of current NASP members are female). Rogers, Ponterotto, Conoley, and Wise (192) surveyed training programs regarding multicultural training in psychology. Approximately 80% of the faculty and students in their survey were Caucasian. Minority faculty seemed to attract minority students; both were more likely to be at universities in urban areas. In discussing the need to include multicultural experiences in training for all school psychology students, Rogers et al. (1992) make the astute recommendation that students in more rural areas may need to arrange practica or internships that include opportunities to work with diverse populations. More research is desperately needed to determine how to interest, retain, and retrain more males, persons of color, bilingual students, and persons with disabilities in becoming school psychologists.

BASIC CONSIDERATIONS

Professional Knowledge

Historically school psychologists have been trained in normal and abnormal child development, learning and remedial techniques, assessment, consultation, intervention, and counseling, research and evaluation, and professional roles. The increasingly chaotic lives of many children necessitate additional content on prevention, educational reform, and crisis intervention. Furthermore, both NASP and APA require that students have a foundation base in traditional psychology as well as in education. Coursework requirements include biological bases of behavior, social bases of behavior, psychopathology, human exceptionalities, organization and operation of schools, and instructional and remedial techniques. Professional school psychologists also must have knowledge of the history of psychology as well as of school psychology, an understanding of ethical and legal issues, the skills to perform diverse roles and functions, and the knowledge and skill to work with increasingly complex technologies. Staying current in any of these areas is demanding. School psychology program faculty must continuously update their knowledge base and skill level in all areas to ensure that students are prepared to make decisions on best practices in their own fieldwork.

Personal Qualifications

School psychologists will be unable to use the knowledge they possess if they do not have good interpersonal skills. Training needs to include *content* and *process* (Conoley & Gutkin, 1986). School psychologists work in an indirect service model; for the most part services are not directly provided to children but behaviors are assessed and recommendations made for others to implement (e.g., special education or general education teaches, parents, administrators). Therefore, training should include how to effectively interact with others through coursework in consultation and social and organizational psychology. In addition, practice through practicum and internship experiences and role modeling by trainers can help students become competent agents for change. Written reports and annual Individualized Education Program (IEP) meeting are not necessarily effective methods of communication, if effectiveness is judged by changes in students' behaviors. Far more footwork, collaboration, sharing of responsibilities, and follow-up are required to target specific problems, design interventions, and evaluate progress. Perseverance, reliability, and interpersonal skills cannot necessarily be instilled during a training program; recruitment of persons demonstrating high levels of these qualities, training them extensively in *what* they need to know, and then modeling and supervising *how* to work effectively with others is most apt to ensure competent graduates.

Practical Experience

School psychologists work in schools; therefore, their practicum and internship experiences should occur in schools, at least at the nondoctoral level (Carey, 1994a). At the doctoral level other settings for internships may be available for experienced practitioners. However, regardless of level of training, to be prepared for the future, school psychologists should be trained to work with preschoolers, families, students of diverse cultures, and students with severe and challenging disabilities. Practicum and internship experiences require close supervision, accountability by both students and trainers, and evaluation by students, trainers, and field-based practicum supervisors.

Furthermore, as Curtis and Batsche (1991) state

> Trainers of school psychologists must become more actively involved with both supervision and professional practice. ... Trainers must work in school and other settings, side by side with students as well as with parents, teachers, administrators, and other professionals. In this way, trainers will be able to engage in necessary retraining along with field-based practitioners. ... Conversely, this shift would facilitate research programs that better meet the needs of the consumers of school psychological services. The link between training and practice would be strengthened. (p. 575)

NASP training standards require faculty to hold doctorates and certification or licensing in school psychology. Faculty are also to have at least two years experience as school psychology practitioners in school settings. They are expected to remain current in the field by professional development and to contribute to the field by research, service, consultation or field experience. We concur with Curtis and Batsche (1991) that faculty need to continue to work in schools, at least periodically, to remain aware of the challenges practitioners face. However, we would take the practical experience component one step further in that we believe trainers should also practice in the field *as* school psychologists in addition to working alongside students. In this way trainers would be personally involved in seeking and evaluating solutions to challenges, rather than operating as outside experts or "consultants" to schools.

Guild Guidance

Credentialing of school psychologists and accreditation of school psychology programs, while separate processes, are related. Credentialing of school psychologists generally occurs at the State Department of Education while accreditation may occur at the state level or in conjunction by the state with NCATE and NASP or APA. The rules and regulations for the required documentation in the process of accreditation require significant amounts of time and paperwork.

The standards for training and field placement programs in school psychology (NASP, 1994) endorse entry at a 60-hour/3year masters/specialist level "at least 54 hours of which are exclusive of credit for the supervised internship experience." To receive NASP/NCATE approval, a school psychology training program must meet these training standards. The NASP training standards require specific coursework content, a designated number of hours for practicum and internship, ad continuous program evaluation. NASP Training Standards can be found in Appendix III of this volume. Training at the doctoral level, based on APA standards, also requires specific coursework content, training in professional ethics and standards, and training in research and design. Credentialing requirements as well as state-level accreditation often vary significantly from that demanded by the professional organizations (Curtis & Zins, 1989). Thus, obtaining accreditation status from the professional organization and the state-level body can require separate processes. For example, in California the state requirements for accreditation of School Psychology Programs are less than those required by NASP. To obtain accreditation at both the national and state levels separate documents must be submitted for review.

BEST PRACTICES

The Scientist-Practitioner

APA and NASP training standards emphasize the scientist-practitioner model. However, training in the scientist-practitioner model has often presented the roles as separate (and perhaps not equal), thereby minimizing the field of applied psychology (Martens & Keller, 1987). Whereas psychologists trained in this model are presumably scientists *and* practitioners, most practitioners utilize their training to evaluate professional practices and rely on faculty and other researchers to actually produce research. Hoshmand and Polkinghorne (1992) suggest a more functional synthesis could be attained, along with enhancing the mutual respect of practitioners and researchers, by examining and modifying the view that research is generated only in formal settings using standard procedures and statistical analyses. Those in Academe might consider expanding the repertoire of acceptable techniques to include qualitative methodology and clinical expertise. This shift would allow practitioners to contribute more fully to the expert base of knowledge and to more readily assimilate research-based knowledge into their practices.

Whereas training in traditional statistical analyses and research design is essential for critically reviewing the literature, practitioners are unlikely to actually implement large *N*-group comparisons. Yet single-case design is not only feasible but an integral part of intervention evaluation. Training programs could emphasize applied psychology as science and include single-case methodology. School psychologists trained in time-series methodology (Barlow, Hayes, & Nelson, 1984; Cooper, Heron, & Heward, 1987) are able to engage in hypothesis testing, contribute to the database on treatments that benefit children, and empirically verify their work.

The Practitioner-Scientist

Best practices charges practice based on scientific research. The greatest controversy in Standards for Training and Field Placement in School Psychology centers around practice issues: Standard 2.4: Interventions/Problem-Solving. Most of the actual daily tasks and requests that school psychologists confront deal with these areas. The orientation of the training program, and the concomitant content of coursework in interventions and problem solving, will guide fledgling practitioners as they venture into the field. In fact, research indicates that practitioners and trainers tend to rely throughout their careers on the techniques and tests learned in their training program (see Lambert, 1993).

In the current NASP training standards, assessment is now termed "Assessment for Intervention," emphasizing the link between problem identification ad problem solving. The *range* and *variability* of assessment courses and content in a program must be evaluated. For example, do courses cover behavioral methods such as structured observations and curriculum-based measurement in as much depth as traditional norm-based academic measures? Are students trained to utilize multimethod and multisource assessment? Is supervision provided on interviewing parents and teachers and on using behavior rating scales? Are assessment instruments designed for use with infants, toddlers, preschoolers, and their families covered? Are students trained to work with multicultural, bilingual students? Is one specific model (e.g., curriculum-based assessment or neuropsychology) emphasized in training versus exposing students to a wide variety of models? Conversely a program can be so eclectic that students have little theoretical focus or orientation to guide practice.

Consultation and intervention, as the core of service delivery, need corresponding emphasis in training programs. A spiraling sequence building on observation, interviewing, consultation, intervention, and therapy techniques is recommended. Training needs to build on prior coursework and incorporate expanded skills in practicum experiences. Students need a conceptual framework, examples of applications, and personal confrontation with the barriers and accomplishments associated with a consultation-based model of service delivery.

A number of programs were founded in counseling, and training in these areas continues to be important. School psychologists trained in social skills, organization, problem solving, or conflict resolution would be welcomed by many teachers. Program faculty need to ensure that counseling training is relevant to the practice of school psychology. Thus, counseling methods with empirical support for use with children need to be taught and practicum experiences provided with children and adolescents rather than adults. Finally, students need an awareness of the limitations of direct counseling with younger children and the feasibility of using parent or teacher consultation and intervention instead.

Practicum and Internship

Standard 3 of the NASP standards, the practicum requirement, addresses the experiences and systematic evaluations in the "practitioner" part of the model, that is, assessment, intervention, consultation, and counseling. Students must be given opportunities to use the knowledge obtained from coursework in applied settings. Internship, addressed in Standard 4 of the document, requires integrated and thorough experiences under careful supervision and evaluation. NASP practica and internship standards term assessment as "assessment for intervention" and include behavior management as a component of intervention. This requirement is consistent with the emphasis on outcome-based services that became a part of the 1994 NASP training standards. In fact, programs are now deemed accountable via outcomes. Students must be able to verbally explain components of school psychological practice, cite legal precedents for services, and defend practices with empirical evidence. Furthermore, students should demonstrate integration of this knowledge throughout practicum and internship by delivering services to children, families, and schools in a skillful and professional manner.

At the specialist level, NASP requires 1,200 hours of internship experience occurring over 1 academic year full-time or over 2 years part-time and 1,400 hours at the doctoral level. APA doctoral level requirements call for a 1,500-hour internship, with at least half of those hours to be completed in a school setting, unless the school requirement has been met through prior internship or experience.

According to the Association of Psychology Postdoctoral and Internship Programs (APPIC; 1991–1992) 123 of the 494 APA-approved internship sites accept school psychologists as interns. Few of these sites are in school districts because districts rarely can provide the licensed supervision required by APA standards. The Nebraska Internship Consortium in Professional Psychology is one of the few internship sites approved by APA that is designed primarily for school psychologists (Kramer, Conoley, Bischoff, & Benes, 1991). Most internships are agreements between school districts and training programs that meet NASP internship standards.

Professional School Psychology

Professional school psychology, Standard 2.6 of the NASP training standards, requires a knowledge base of the professional speciality. This section encompasses the history of school psychology, legal and ethical issues, and the role and functions of school psychologists under various models of service delivery. Ensuring that school psychologists are well prepared to enter the field is only a good start. An important area often overlooked is that of continuing education. (For additional information, see the chapter by Fowler in this volume.)

Bandwagons seem to come along frequently in education and as professionals, school psychologists should have the skills and knowledge to carefully evaluate the usefulness of innovative practices. We must remain open to new ideas and techniques and to antithetic points of view throughout our careers and make decisions about training and practice based on research and experience rather than rigidity or naïveté.

Surveys over the years have found new changes in the assessment tools practitioners are using (Carey, 1994b; Goh, Teslow, & Fuller, 1981; Hutton, Dubes, & Muir, 1992; Wilson & Reschly, under review). Actually, it is unethical to use instruments and techniques with students without adequate training in their use. Therefore, continuing education is not only desirable but necessary.

Curtis and Batsche (1991) recommend more flexibility in university training programs to facilitate ongoing training for practitioners. The NASP standards are designed to both require and offer opportunities for the updating of skills through workshops, conventions, and the like. In-service training may be the most efficacious way to train psychologists in working with low incidence populations, such as individuals with severe disabilities (Mar, 1991). Reschly and Grimes (1991) describe a model of statewide in-service used to update practitioners in the areas of consultation and curriculum-based assessment. Postservice training must involve more than listening on the part of the trainees; actual practice and follow-up are necessary for skills to be mastered.

Future Directions

Entry-level preparation, in terms of level and specialization, continues to be debated. Phillips (1990) asks

> Will school psychology be an occupation that continues to play a role limited largely to assessment and determinations of special education eligibility? Will school psychology become a two-tiered occupation, consisting of doctoral school psychologists increasingly engaged in a variety of nontraditional (and nonschool) roles and nondoctoral school psychologists who continue to be engaged in the traditional assessment role? Or will school psychology become a speciality and profession that reaches for new roles, that raises the academic standards of training programs and the practical competence of its members, thus engendering prestige, compensation, and working conditions good enough to be recognized as a specialty and profession of first class? (p. 252)

We consider school psychology presently to be a first-class specialty and profession. However, to meet the needs of children today and the challenges of tomorrow, we agree that our roles, at both the subdoctoral and doctoral levels, must expand beyond that of special education gatekeepers.

Epstein (1992) provides a model for school psychology in the 21st century in which school psychology is responsive to the needs of students, families, and schools. This is analogous to a new NASP Training Standard, 1.2, which states that programs should train school psychologists to deliver services sensitive to the needs of families and schools. Thus, school psychologists must be knowledgeable in the areas of child development and educational practices and able to advise parents, facilitate workshops for educators, and serve as coordinators for multiyear plans, communicators and coordinators with parents, and evaluators of programs and school climate. Only through comprehensive training will school psychologists be partners with teams of educators and parents. As psychologists of the school, we will be responsible for developing environments that prevent problems and promote mental health. This must be the focus of our training: a view of the future that actually takes us back to our roots (Fagan & Wise, 1994; French, 1990; Woody, LaVoie, & Epps, 1992).

SUMMARY

The challenge of providing services to students in schools is becoming extremely complex. Increasingly children are entering our schools "at risk" for academic, social, and emotional difficulties due to a multitude of societal changes and problems. To meet the needs of children we must, as school psychologists, continually update our skills and stay current in the field. To facilitate this, trainers of school psychologists must remain active in the field through practice, service, and conducting and evaluating research; practitioners must engage in continuing professional development through workshops, training programs, and readings; and students must be provided with state-of-the-art education with an understanding that training today will not be sufficient for serving children tomorrow. Change and learning are life-long processes.

Best Practices in Serving as an Expert Witness

James M. Stumme
Heartland Area Education Agency
Johnston, Iowa

OVERVIEW

School psychologists are becoming increasingly involved in the legal system and are called upon to testify regarding psychological evaluations, treatment procedures, and special education programs, and to make recommendations regarding particular cases. School psychologists have testified in a variety of legal arenas, such as, due process administrative hearings, state civil courts, state criminal courts, and federal district courts. This testimony has been rendered on a wide range of issues, such as, disability eligibility, appropriateness of placement options, appropriateness of IEPs, degree to which responsibility for criminal acts was diminished by disability conditions, test bias, alleged discrimination against minority students, and many others, In addition, school psychologists are involved in less direct legal matters such as giving professional opinions on what constitutes acceptable professional practice (Shapiro, 1984). For example, a school psychologist may be requested to evaluate for a malpractice suit whether a mental heath practitioner demonstrated acceptable professional practice. Similarly, another related role the school psychologist can serve is that of consultant to the legal system in the form of reviewing and critiquing a psychological evaluation/intervention performed by another professional for the specific purpose of furnishing the opposing attorney with information for cross-examination.

Whether or not school psychologists appear in court on any of the above topics will likely depend on the kind of assignment and population they serve and what someone else wants to do with or about these clients. Professional preferences or even selected areas of expertise occasionally do *not* determine the issues that school psychologists may be required to address in court.

Unfortunately, traditional school psychology training programs do not provide practitioners with knowledge or practice that will prepare them to provide competent court interventions. Graduate coursework on professional issues and ethical concerns tends not to present more than perfunctory treatment of the role of the school psychologist in the legal system, the psychologist/lawyer/client relationship, or the expert witness role. Tymchuk et al. (1982) concluded from a survey of clinical psychologists that only 37% of the survey participants received formal, structured modes of learning in professional issues and ethics. The naive practitioner may unknowingly plunge from the relative safety of daily routine and familiar school territory into the unknown legal arena and threatening environment of the witness stand. Once on the witness stand, school psychologists can potentially have their credentials belittled, their testimony rigorously interrogated, their opinions subject to ridicule, and if not thoroughly prepared and schooled in the ways of the court, their self-esteem and professional credibility tarnished. It is in this context that this chapter has been written.

The purpose of this chapter is to acquaint the school psychologist with the special procedures, techniques, and considerations necessary for providing effective courtroom interventions. More specifically, this chapter will address the most common court interventions rendered by school psychologists, namely, the provision of expert testimony and how to construct and submit written reports.

BASIC CONSIDERATIONS

The essential purpose of any testimony is to provide useful and relevant information to the court to assist it in making an informed legal decision (Schwitzgebel & Schwitzgebel, 1980). Hopefully this process can be accomplished with a minimum amount of stress on the expert witness. This is possible only when the expert witness is knowledgeable of the court process and is adequately prepared. An uninformed and unprepared witness is in the unforgiving hands of the adversarial counsel. The following information, suggestions, and considerations are presented to assist school psychologists in their preparation to assume the role of the expert witness.

The Lay Witness Defined

There are two distinct categories of witnesses, lay witnesses and the expert witnesses. Lay witnesses may testify only to phenomena which they have legitimately seen, heard, felt, tasted, or smelled directly. The general rule is that the lay witness is prohibited from testifying about anything other than that gained from personal perception (Westphal & Kohn, 1984). A lay witness may not in testimony express opinions or draw inferences unless the court finds that these can be rationally based on the perception of the witness and that they are helpful to understanding the witness' testimony. "Thus, lay opinion evidence as to distance, time, speed, size, weight, direction, form and identity are admitted; if such opinions are of a type which a normal person forms constantly and correctly" (Cook, 1964, p. 459). Expressing conclusions is not within the scope of lay witness testimony and is, in fact, the function and burden of the court.

The Expert Witness Defined

In contrast to the lay witness, who may testify primarily only on first-hand perceptual knowledge, the expert witness may in testimony formulate and express professional opinions and can draw inferences from data. Experts are asked to testify because they have special knowledge, training, and experience beyond that of a lay person. They possess something unique to contribute. The expert witness is limited, however, to opinions or inferences about matters which are perceived by, or personally known to, the witness. The information presented must also be within the scope of the witness' special training, skill, and experience to interpret, and be of direct aid to the court (Cook, 1964). For an example of the professional specificity of such testimony, consider the expert witness who was requested in a criminal case to testify on "how the development, adaptations, and function of [the] defendant's behavior processes may have influenced his conduct" (*Washington v. United States*, 1967). Or consider the expert who was, in a civil commitment hearing, asked to "explain the development and manifestations of the alleged mental illness and also probably to make a prediction about the individual's 'dangerousness' to self or others" (Schwitzgebel & Schwitzgebel, 1980, p. 238). Although specificity is necessary to address many professional issues, it should be tempered with explanations that the lay public can understand. Simply asserting a professional conclusion (e.g., the individual suffers from schizophrenia) is not, in and of itself, adequate (*Carter v. United States*, 1957). In essence, expert testimony is admitted only when it assists the trier of fact (a jury or judge in a nonjury trial) to understand and analyze evidence or to determine a fact (Federal Rules of Criminal Procedure, Rule 702).

Brodsky (1991) and Brodsky and Robey (1973) describe and examine two extremes of expert witness behavior exhibited by mental health care professionals. They dichotomize these two distinct groups as the courtroom-oriented expert witness and the courtroom-unfamiliar expert witness. The courtroom-oriented witnesses are portrayed as behaving in desirable ways, while the courtroom-unfamiliar witnesses conduct themselves in comparatively undesirable ways. Gorlow (1975) summarizes the former as possessing some legal training, having some knowledge of the law, displaying minimal emotional reaction to subpoena, speaking in clear and concise language avoiding jargon, and representing their position with restrained advocacy. Gorlow characterizes the courtroom-unfamiliar witness as possessing no relevant legal training and as being unaware of law and evidence rules, showing personal distress in response to subpoenas, representing their findings in technical jargon, demonstrating fierce advocacy, and responding with resentment and anger to cross-examination.

Prior to authorizing an expert witness to express an opinion, inference, or conclusion, the court must be assured of two prerequisite conditions: (a) the expert testimony is necessary to fully understand the evidence or to determine a fact in evidence, and (b) the expert witness possesses the necessary credentials to adequately form an opinion, inference, or conclusion (Westphal & Kohn, 1984). The requirements needed by a school psychologist to meet the specific qualifications of an expert witness differ from case to case and range from the most rigorous credential inquiry to a cursory review. In a case cited by Schwitzgebel and Schwitzgebel (1980), the conviction of an accused murderer was reversed in part because the prosecution's psychologist did not possess a PhD degree, 5 years of postgraduate training in clinical psychology, and a 1-year American Psychological Association-approved internship. Nonetheless, since each case is handled differently, the chief factor in determining the credentials required of the expert witness is the matter before the court. If, for example, the case involves expertise in the area of the most appropriate and least restrictive alternative in special education placement, the school psychologist might be deemed by the court to have specialized qualification and, indeed, an expert worthy of providing testimony.

Even if a particular psychologist is considered the utmost authority for a given case, she or he must be adequately prepared for a courtroom appearance. If not, the results could be disastrous. The court system is not kind or sympathetic to the unprepared.

BEST PRACTICES

Pretrial Preparation

Optimal courtroom performance is accomplished through the combination of implementing competent best practices in the delivery of all pretrial professional services and thoroughly preparing testimony material prior to taking the witness stand. Diligent pretrial preparation greatly alleviates harmful courtroom stress, is ethically responsible, and can have a potentially positive impact on the esteem others hold for the profession of psychology. Adequate pretrial preparation covers a wide diversity of activities, which are examined in the following discussion.

Selection of the expert witness. A psychologist may be requested to testify as an expert by the court system or by attorneys representing either the plaintiff or the defendant. Experts may be chosen because of past work with a client or because of their area of specialization, such as assessment of chemical abuse, assessment of child abuse, or knowledge about developmental disabilities. Some jurisdictions even retain organized pools of mental health experts, which they reimburse on a fee-per-case basis (Schwitzgebel & Schwitzgebel, 1980).

Information gathering. Just a word of caution. No pretrial preparation is complete without scrutinizing all gathered information for possible trouble spots or holes. Any questions that are unanswered should be answered. It is better to tackle these during preparation than during cross-examination. Any information gaps can furnish the opposing counsel with ammunition to contest the expert's credibility and ensuing testimony. A cursory reading of a record can cause the expert to miss some important point(s), which can greatly discredit testimony on the stand (Shapiro, 1984). In addition to checking records and other gathered material, the expert witness must make sure the person seen is the person who was referred. There are examples of mistaken identity. The expert providing testimony should never leave the session during an assessment, nor should an associate, assistant, practicum student, or intern be allowed to administer an examination. The expert witness must be confident of the source of information to avoid any suggestion by the opposition that an outsider wrongfully prejudiced the results (Schwitzgebel & Schwitzgebel, 1980).

Information dissemination. In both civil and criminal cases, all parties are allowed the opportunity to receive the names of expert witnesses and their findings prior to their testimony, which eliminates any unexpected revelations. In fact, some court systems require the attorney to list their witnesses, a summary of their evidence, an estimate of the time required for witnesses' testimony, and the intended order in which the witnesses will be called — all in written form to be submitted to the court prior to even a pretrial conference (Cook, 1964). Although it may be appropriate for an expert witness to dialogue with the opposing lawyer, it is imperative that the expert witness contact the client's attorney prior to the meeting to allow the client's attorney the option of attending. Conservative practice would dictate that all communication with the opposition's attorney should be conducted through the client's attorney. In the case of a school hearing, the school attorney would need to be notified. No written correspondence should be delivered to the opposition without the express written consent of the client's lawyer (Westphal & Kohn, 1984).

Since there are few limitations for restricting the dissemination of expert witnesses' findings, there is some danger that information harmful to the client's case will be obtained by the opposition. This information could potentially help the opposition both build a case against the client and find weak areas in the expert witness' testimony. However, it should be noted that there is a thin line between professional conduct as an expert witness and advocacy. It is unethical for a psychologist to misrepresent testimony for a client's cause. By concealing information, the expert witness becomes an advocate of the client rather than an advocate of the facts. The former constitutes questionable ethical practice.

Utilization of files, records, and the face sheet. Any files, records, or personal notes that are brought to the witness stand by the expert witness can be obtained by counsel for the opposition and used as fuel for cross-examination. The opposition simply asks to have the expert's files and records admitted as an exhibit so that the court may more thoroughly examine them. Because of this open-record policy, expert witnesses should bring with them only file and record information that will assist them in their testimony and that will hold up under the most exhaustive adversarial scrutiny. File information that is not relevant to the case should not be brought to the witness stand, as it can be a source of potential embarrassment to the client and make it difficult for the expert witness to stay within ethical boundaries. According to Shapiro (1984), one of the favorite ploys in cross-examination is to ask expert witnesses if the notes they have on their person are all of the notes that they took during the examination. The cross-examining attorney will then obtain the notes and compare them to the written report submitted by the expert. Any notes left out of the report will then be attacked in a highly accusatory manner in which the expert witness will be requested to state why some notes were included and interpreted in the report and others were not. One defense strategy for this tactic is for the expert witness to take only carefully selected handwritten notes on the file to court. Another defense when discrepant material is found between personal notes and the written report is to state that only that information which, in the expert's opinion, is clinically significant is included in the report (Shapiro, 1984).

Although handwritten notes are preferred by most expert witnesses, there are circumstances when entire files must be taken to the witness stand (i.e., the subpoena of school records). In such situations, it is imperative that the expert witness thoroughly know the files and how to quickly locate every piece of information within them. Moreover, the expert witness must be prepared to defend how opinions and inferences are supported by the documentation within the files and why discrepant information within the files is not considered clinically relevant.

A good tool for organizing written files, records, and personal notes is the face sheet. The face sheet is a 1- to 2-page outline that summarizes quantitative data such as the number of sessions with the client, beginning and ending dates, etc., along with a brief summary of findings, impressions, opinions, conclusions, and recommendations. In addition, it is helpful for expert witnesses to list on the face sheet all information they feel is important to bring out in court. The face sheet can be of great assistance for quick reference when, under the stress of cross-examination, the mind goes blank.

Legal consultation and preparation. An important pretrial preparation that should not be overlooked is the consultation between the expert witness and the attorney of the client. This is an educational process. The attorney has been schooled to carefully prepare the expert witness for testimony but may not know how to deal with psychological data. In juvenile cases, chances are good that the expert witness will have a young, inexperienced lawyer. The expert witness may need to educate the lawyer on the best ways to present the data. Do not assume the client's legal counsel knows what questions to ask or even the best way to ask them. This may not be the case. And a lawyer who does not know to ask might ask questions that could harm the expert witness' testimony. An expert witness' testimony might be potentially compelling, but unless the correct material is prompted by the lawyer's questions, it will not be heard. Moreover, an expert witness can appear foolish. It is therefore imperative that the expert witness outline for the attorney the information the expert wants to get across. A list of tentative questions to the attorney is certainly appropriate but not if the list contains answers. If answers are included, it is considered scripting, and scripted dialogue could find its way to the opposition's counsel. The list of questions should allow for responses to be elaborated and systematically build toward the desired culmination. Although it is not appropriate to script dialogue, there is nothing wrong with role-playing possible courtroom scenarios that could occur with the client's counsel.

One problem that must be addressed with respect to consultation with the client's counsel is the accusation that may be made that the lawyer somehow influenced the expert witness' findings. Shapiro (1984) suggests that the expert witness should respond to this by stating that, in the course of the pretrial consultation, the expert witness communicated his or her findings to the attorney after completing an evaluation and reaching an opinion. It is best practice to document the exact dates of services to the client, establishing an opinion, and consulting with the client's lawyer.

Presentation of professional credentials. Prior to asking the psychologist to give expert testimony, the court must establish that the witness does, in fact, possess the necessary educational credentials and experience to qualify as an expert witness. This will be done on the witness stand and requires careful preparation prior to being sworn in.

The expert witness should meet with the client's attorney and provide an outline of credentials or a vita that carefully lists:

- formal education and degrees
- specialized training including practica and internships
- areas of research and publication
- professional affiliations and offices held
- assistantships, fellowships, and work experiences

Often the attorney will review the expert's credentials one at a time in court to give the expert an opportunity to tell of his or her expertise and accomplishments. The manner of presentation will in no small way determine the credibility of the expert witness. According to Westphal and Kohn (1984), the psychologist does not need to be world famous or the author of a book on the subject to be admitted as an expert. But the psychologist's evaluation methodology and resulting opinions should generally be similar to the conclusions of others in the same field.

The lawyer for the opposition will be afforded an opportunity to cross-examine the expert witness about credentials in order to invalidate or limit the expert's testimony. A strategy for limiting the expert's testimony is to call for a stipulation of qualifications. When an opposing lawyer asks to stipulate, she or he is probably trying to keep the trier of fact from knowing the breadth of the expert witness' qualifications (Shapiro, 1984). This tactic avoids giving the expert witness too much credibility. The psychologist should request the client's attorney not to allow stipulation should it be requested, in order to allow the court to hear the expert witness' full credentials.

When actually presenting credentials to the court, it is important not to understate or to minimize qualifications, because the credibility and effectiveness of one's testimony is reliant on them. Likewise, overstatement and arrogance can be detrimental to one's effectiveness as an expert witness.

Use of visual aids. Like the clarity and visual impact provided to psychological reports by graphs and charts, visual aids can assist in explaining data to the court system. The salient difference is that the visual aids utilized in the courtroom must be targeted at a lay population and free from technical jargon. Other than that, courtroom visual aids can run the gamut from large poster presentations to individual handouts.

Courtroom conditioning. The more familiar the expert witnesses are with the courtroom environment and principal actors in that environment, the better their performance will be. Under ideal conditions, it is helpful to visit the specific courtroom and become familiar with the location of the judge's bench, jury box, and witness stand. It is good practice (conditioning) for expert witnesses to sit where they will probably sit before being called to testify and to practice walking to the witness stand. Sadly, some expert witnesses have adequately prepared their presentation, worn their most professional suit, and then had their confidence shaken and their credibility questioned when, as they approached the witness stand, they could not open the gate separating the observers from the trial participants. The unknown can be unnerving! It is important to learn as much about courtroom procedures as possible before the day of the hearing. For example, if expert witnesses are Jewish and are asked to place their hand on the Bible and to tell the truth, they will be facing their first dilemma. Another piece of information the expert witnesses would want to know is whether reporters will be present or any other media coverage is planned. Expert witnesses can handle almost anything as long as they are informed of possible scenarios ahead of time.

Along with knowledge of the physical environment, it is equally important for expert witnesses to have information on the identities, roles, and personalities of the other principal actors that they will interact with in court. For example, in a jury trial the judge will act as referee, the jury will be the decision makers, the lawyers the advocates and persuaders, and the witnesses the information providers. In a nonjury trial, the judge will be both referee and decision maker. More than just knowing the roles people will play, it is extremely important to know how the specific judge and representing attorneys are likely to conduct themselves in court. If, for example, expert witnesses know that an attorney typically tries to intimidate a witness, they can be prepared and not take it personally. Likewise, knowing that a lawyer typically sets witnesses up by trapping them with apparently simple questions will alert the witness to the need for caution. In determining how to present information in a way the judge will consider effective and determining the person to whom responses should be presented, law clerks and bailiffs can be an excellent source of information.

Dress and demeanor in court. An expert witness' acceptability and credibility are contingent on numerous easily overlooked variables. One influential variable is dress. Expert witnesses apparel and accessories should add to their role as competent experts, not diminish the impact of their testimony. A dark suit or dress is traditional and desirable. Outlandish, eye-catching clothing should be avoided. Dress is like a billboard and advertises the wearer's role, status, and personality. The more uniform the clothing, the more it emphasizes the person's role and decreases the importance of personality. The image the expert witness wants to portray for role is professional and competent, for status is middle class, and for personality is pleasing, objective, empathetic, and intelligent.

Another powerful variable, one apart from the substantive issues covered during testimony, is the expert witness' demeanor. The witness should be confident but not cocky. The expert witness is not on trial, but the expert's opinions and inferences will be questioned, and this can be unnerving. It is best to try not to show too much emotion. Exaggerated displays of emotion are unprofessional and give the appearance of a personal investment in the outcome of the case. The expert witness is an advocate of the facts, not the client.

Although dress and demeanor can potentially add to or subtract from an expert's credibility, the expert witness should be aware that the most important aspect of testimony is to help the court system by providing accurate, understandable data. An expert witness can look good and sound professional, but not help anyone.

Expert Testimony: The Direct Examination

The school psychologist at this point has implemented best clinical practices; formulated opinions, conclusions, and recommendations; and painstakingly prepared to present data in understandable lay terminology. The clinician is then called to the witness stand, sworn in, and questioned by the attorneys representing both the defendant and the plaintiff to establish the witness as an expert witness for the specific case at hand. It is now time to proceed with the direct examination of the expert witness.

The adversarial process. The adversarial process is a concept foreign to the mode of operation of most school psychologists. The range of acceptable behavior for attorneys is distinctly dissimilar to that of practitioners in behavior sciences. The adversarial process places a much different expectation upon lawyers than upon mental health professionals (Schwitzgebel & Schwitzgebel, 1980). "Psychologists

TABLE 1
Ethical Code and Principles for Psychologists and Lawyers

present the science of psychology and offer their services, products, and publications fairly and accurately, avoiding misrepresentation through sensationalism, exaggeration, or superficiality" (American Psychological Association, 1981, p. 635). The ethical code of lawyers is much different and charges them to present evidence as one-sided as possible to win their case. Attorneys will use any part of the law that will be most beneficial to their case; it is their absolute duty. Within the confines of the law, an attorney will attempt to force the expert witness to make definitive specific statements about behavioral data. This holds for the client's lawyer as well as the opposition's counsel. School psychologists, in the role of the expert witness, know there is a range of accuracy in behavioral science that does not allow absolute specificity. This impasse is where lawyers and psychologists clash. Psychologists must be on constant guard to maintain their ethical standards within the adversarial framework of the courtroom. Table 1 contrasts the ethical codes and concomitant principles for the professions of psychology and law.

Advocacy. If the school psychologists believe that they are, in fact, scientists, then they must not be advocates of a client, a school, or a state agency, but rather advocates of the data. The expert witness is an advocate of objective facts. The practitioner as an expert witness should be emotionally tied only to providing impartial facts. It is an irrational belief that the expert witness must defend one side or the other. When independent witnesses for the court have strong emotional feelings about a client, they frequently respond differently to defendant and prosecution questions, which inevitably harms their credibility as an expert witness. Table 2 highlights the substantive differences in the advocacy role for psychologists and lawyers.

One aspect of advocacy must be clarified. It is generally not considered good practice for a psychologist to become an examiner for a client he or she is seeing or has seen, for therapy. As a therapist, the practitioner is an advocate for the client, but in the courtroom the school psychologist must become an advocate of the facts. Discussing these facts impartially in public could destroy the therapist–client relationship and ultimately harm the client. Referral at this juncture is usually deemed most prudent. Clarification with the client of the psychologist's role and parameters of confidentiality prior to rendering any professional services is ethically responsible.

Responding to questions. Under direct examination it is appropriate for the expert witness to look directly at the person asking the questions and respond verbally back to the person in a direct, honest, and candid manner. It is sometimes difficult to talk about defendants when they are physically present in the courtroom. This can be rectified by occasionally talking to them during testimony as if giving them feedback on the evaluation. On long responses it is desirable to make eye contact with the judge and jury. On short answers, eye contact with all courtroom actors is awkward and experts could find themselves continually glancing around the courtroom.

The expert witness is required to respond verbally. Hand or head gestures are not acceptable and the court will ask the witness to emit a verbal response.

In giving testimony, experts should be concise to avoid lessening the importance of their information through too many words. To promote communication, they should minimize technical jargon and explain technical terms when their use is absolutely necessary. Professional terminology that has a different lay meaning should be carefully defined. Examples include depression, deterioration, and within normal limits (Shapiro, 1984). The judge is a trained listener, and any condescending or patronizing comments will not be well received. Likewise, the expert

Detached from emotion	Strive to use emotion for client's benefit
Impartial	Partial

witness should refrain from flippant remarks or attempts to be amusing. The expert witness wants to be seen as professional and competent, not as a witty comic.

The best verbal response in the world is useless if it is not directed to the question that was asked. The expert witness must listen diligently to the question posed before responding. If the question is unclear, the expert should request that it be repeated, explained, or rephrased. The expert witness has the right to have questions repeated and words or phrases explained.

There are different opinions as to whether an expert witness should answer only the specific questions asked or volunteer additional information. The former opinion is based on the thought that the lawyer has a specific order of questions and will use that order to most effectively utilize expert testimony. Breaking that sequence by volunteering information will be detrimental to the impact of the testimony. The latter view holds that expert witnesses should use questioning as a guide for their responses and present, within general boundaries, that information which they feel is most relevant. At any rate, if expert witnesses are asked an open-ended question, they should use that opportunity to build, fortify, and elaborate on their findings and conclusions. Lawyers are frequently taught to never ask "why" questions. According to Shapiro (1984), "why" questions are an opportunity for the expert witness to take as much time as necessary to explain something as fully as possible. The expert witness who would like to cover more information than requested can ask for permission to elaborate on the subject. If the attorney says yes, it is permissible to proceed. If the attorney says no, it signals the opposing attorney and judge that the questioning attorney is not being fair, and that the judge or opposing attorney can follow up with questions or directions to the expert to elaborate. Expert testimony is not like that which is exemplified in television drama. The expert does not have to answer just the question posed. The judge will not allow the lawyers to control the type of information that is introduced. The judge is interested in knowing whatever helpful information the expert has and this information will be allowed to be aired. Likewise, the judicial system will not stipulate that the expert respond with only a yes or no answer if that response would be misleading (Cook, 1964).

When expert witnesses do not know the answer to a question or do not have an opinion, they should not speculate or render a haphazard guess. Rather, they should attempt to rephrase the question so it becomes one to which they can respond. In regard to giving an opinion, expert witnesses should only give opinions when they have carefully considered all available evidence. There is nothing wrong with requesting time to consider new information. To respond without careful deliberation sets the expert witness up for potential difficulties. In addition, making seemingly quick decisions undermines the validity of the professional's carefully thought out and considered opinions.

The expert witness should be cautious about answering questions with one-word responses. One-word responses, although simple, are open to too many interpretations and assumptions. For example, if the witness responds with yes to a question, does this mean yes for every situation like this one or just yes for this specific instance? In addition, one-word answers can build a response set that allows the lawyer to ask many questions very rapidly and allows the lawyer too much control over the direction and rate of questioning. An alternative method of responding for the expert witness would be to simply repeat or rephrase the question before responding. This provides the expert with more control.

If at a later time in their testimony, expert witnesses feel they have given misleading or inaccurate information, they should amend their statements as quickly as possible.

Presenting limitations and contradictory data. Expert witnesses should make a substantial endeavor to anticipate in advance of their testimony the areas of testimony in which they appear weakest and could be challenged (Shapiro, 1984). They should then present the limitations of their evaluation and findings and any seemingly contradictory data in a very orderly manner during the direct examination. This is a much preferred mode of operation to appearing bewildered and distressed by challenges during cross-examination. Handling potential trouble spots during direct examination is more comfortable and controlled than during cross-examination, gives the professional more credibility, and adds to the potential strength of the testimony.

Expert witnesses should present the limits of their involvement with the client by describing the dates they saw the client, the number and length of their sessions, and their relationship with the client prior to, during, and after the evaluation. In addition, they should further specify the exact nature of their intervention. If, for example, they did a chemical dependency evaluation on a child, they would not address questions about whether a particular parent should have custody of the child, nor would the court expect them to. Expert witnesses should not render an opinion on a subject unless they have done an evaluation on that particular subject.

When there are apparent contradictions in the data, expert witnesses will want to present these contradictions and explain how they have reconciled contradictions with their findings during the direct examination. This will demonstrate to the court their awareness of the issues and that they have carefully considered the issues, evaluated their significance, and assimilated that information into their findings and opinions (Shapiro, 1984).

Expert Testimony: The Cross Examination

Cross examination is without question the most feared of all courtroom experiences, and for good reason. Graduate students in their oral defense are treated better and challenged less than an expert on the witness stand. There is no collegial status within the courtroom for a mental health practitioner as an expert witness. The adversarial environment of the legal system is engineered so that at all times one side carefully listens to testimony for evidence of support while the other listens to systematically tear the testimony down. Some attorneys in their cross-examinations use blatant ridicule, while others are more effective in methodically weakening or destroying an expert's testimony by more subtle means (Ziskin, 1975). Either way, expert witnesses must be prepared and aware of typical attacks, common traps, and strategies in order to successfully hold their own during cross-examination.

The attack. There are many different techniques attorneys use in cross-examination. While some prefer to berate the expert witness personally, other lawyers choose to not assault the opposing professional too adamantly because the repercussion could undermine their own expert witness' testimony. Thus, most lawyers tend to be very discriminating about how they cross-examine the expert witness (Shapiro, 1984).

To keep the expert witness from becoming defensive and taking cross-examination too personally, Shapiro (1984) has offered the following guideline. The attorney's first inclination will be to attack the expert's opinion. If that opinion is strongly supported, the attorney will attack the expert's credentials. If the expert's credentials are beyond approach, the attorney will then be forced to attack the expert personally. So if experts feel they are being attacked personally they can feel reasonably confident that their credentials and opinions are sound. This frame of reference will allow expert witnesses to assess the strength of their case by the level of attack of the cross-examining lawyer.

Common traps. Cross examining attorneys occasionally trap expert witnesses by baiting them with questions about tangential and unrelated information in an attempt to undermine the expert's credibility and testimony. One common trap is for the lawyer to present the expert witness with an obscure article or research study and ask the expert if she or he is familiar with it and how it relates to the particular case. When this happens, if experts are aware of the article they should acknowledge it and discuss the findings of the study. If the findings are different than the expert has concluded, the expert should cite other research which supports their findings, and be prepared to analyze the study and state why the findings are not applicable in this case (Shapiro, 1984). If experts are not aware of the study, they should simply say so.

Another typical ploy by the cross-examining lawyer is to pose a hypothetical situation and ask the expert to comment about it in regard to the expert's findings and conclusions on the case at hand. This is a trap. As was stated before, experts should not render an opinion on an evaluation they did not do. The expert witness should state that any hypothetical situation would contain too many unknown quantities and that the professional does not make decisions without careful research, study, and evaluation. Speculation is simply speculation and should not be made by a behavioral scientist without data.

A closely related trap employed by a cross-examining lawyer is to ask the expert witness to make a generalization based on data the expert compiled during evaluation. For example, the attorney might say to an expert, "Isn't it possible, based on your observations, that . . . could happen?" Once experts go along with this line of questioning, they will have a difficult time at where to draw the line and stop. Taken to extremes, these generalizations can greatly harm the expert's carefully thought-out, considered opinions. One response might be for the expert to declare, "Anything is possible." But this brash comment may be counterproductive, antagonize the lawyer and judge, and not help with the professional image the expert hopes to project. An alternative response that could potentially strengthen the expert's credibility would be, "Although that is possible, given the evaluation which I conducted, it is my opinion that . . ." (Shapiro, 1984).

Cross-examining lawyers will also try to isolate one symptoms, behavior, or specific test variable and ask the expert witness how that piece of evidence contributed to the expert's opinion. To avoid this trap, the expert witness should respond by stating that their opinion on the individual client was derived by assimilating the totality of information available to them from many various sources and not based on any one specific piece of data.

Expert witness strategies. In direct examination, the lawyer cannot lead the expert witness, but during cross-examination the attorney can and will lead the witness. The expert witness must therefore have a ready supply of proactive strategies to cope with the onslaught during cross-examination. The following strategies and suggestions are offered to aid the school psychologist preparing for cross-examination.

Preparation, preparation, preparation. The expert witness should know their theoretical orientation, know the related literature and research, and be able to adequately describe the assessment process they conducted. The cross-examining attorney will probably not attack the expert's conclusions, but rather the scientific adequacy of the method used to derive those conclusions (Schwitzgebel & Schwitzgebel, 1980). It is important to remember during cross-examination that it is the expert who has the knowledge of the field, and that knowledge can be used to the expert's advantage. Here is an example of cross-examination interchange from Shapiro (1984, p. 81).

> Attorney: Now, then, doctor, hasn't research shown that the MMPI is invalid?
>
> Expert: I really cannot answer that question; would you be able to define what you mean by validity?
>
> Attorney: Come now, you're a doctor, don't you know what valid is?
>
> Expert: Certainly, counselor, but there is predictive validity, construct validity, and face validity — to name only a few. You will have to define your terms more precisely before I can respond to the question.
>
> Attorney: I withdraw my question.

Expert witnesses should acknowledge their beliefs, weaknesses, and sympathies honestly and without undue hesitation. They need not appear embarrassed by them. Admitting weaknesses will not undermine their credibility and can, in fact, make them more creditable and believable.

The expert witness should respond in terminology that is easily understood by the courtroom participants and resort to esoteric jargon only when absolutely necessary. Many people are skeptical about experts anyway, so the less jargon, the more acceptable the expert's testimony will be.

As in the direct examination, expert witnesses will need to listen to questions carefully during cross-examination. If a question cannot be answered as asked, experts should say so and ask to have it rephrased or rephrase it themselves. This latter option gives the experts more leeway; they can shape the question to fit their response. If the question has more than one part, experts will need to be sure to answer each part specifically, and if they have additional information that would be helpful to the case, they should also try to work it in.

Cross-examining attorneys will attempt to intimidate and control the pace of their questioning. To counter this, expert witnesses should set their own tempo by pausing to carefully think before responding, and by restating or rephrasing the question. In addition, sustained periods of time testifying can be fatiguing, can contribute to nervousness, and can produce anger, carelessness, and a willingness to say anything to get off the stand (Westphal & Kohn, 1984). If experts sense any of these symptoms, they should request a short recess.

The best preparation of all for cross-examination is to thoroughly use direct examination to the fullest. This involves the client's attorney and the psychologist spending time together planning how to most effectively present the data in order to achieve the greatest clarity and most persuasive presentation possible. The expert should instruct the attorney to follow up any stated opinions with a question to the expert asking the expert to state the grounds and basis for the opinion (Shapiro, 1984). This will allow, hopefully in the direct examination, the expert to present as much information as possible to fortify and explain their inferences, interpretations, and conclusions. If this information is not presented in the direct examination and only brought out during cross-examination, experts appear defensive and their testimony weaker. The more comprehensive the testimony during direct examination, the less stressful and challenging the cross-examination will be.

Other Considerations

Sometimes it is the little pieces of information that separate the good expert witness from the excellent expert witness. The following information is presented to promote the latter.

Rule on witnesses. It is usual practice during lay testimony for the lawyer to ask the judge for a "rule on witnesses," which means that everyone else testifying on the same concern is to be excluded from the courtroom to avoid one testimony influencing another. It is entirely within judges' discretion to determine if they will apply this rule to expert testimony (Shapiro, 1984). If a judge should apply the rule on witnesses to expert testimony, the expert should not be insulted or upset but rather just accept this as standard courtroom practice and gracefully leave the courtroom chambers.

Fee considerations. To avoid any misunderstandings, a fee for the expert's evaluation, report writing, preparation, and testimony should be established and paid before actual testimony takes place. This will eliminate any possible implication that the fee is contingent upon the expert's testimony, which could be challenged in court (Schwitzgebel & Schwitzgebel, 1980). However, it is certainly appropriate for experts to submit a bill for their time in court afterward, as they would for any professional service they provide.

Unexpected outcomes. Sometimes court rulings are hard to understand. No matter how prepared expert witnesses are and how impressive their court performance, the court can rule in a seemingly unpredictable and incomprehensible manner. This can happen for a number of questionable and uncontrollable reasons. For one thing, judges are only human. The particular judge may have had previous contact with the defendant or plaintiff either in or out of the legal system, which could be either beneficial or detrimental to the case. Or the person on trial could be a well-known personality in town. This too could be good or bad.

Also, facts today are not facts tomorrow. History is laden with examples of things considered undeniably true, scientifically proved and backed by the best minds, that were ridiculed, abandoned, and scientifically disproved at a later date. It is for this reason that the field of law is extremely cautious about accepting something as absolutely, ultimately true until it has been demonstrated to be unquestionable by the passage of time (Cook, 1964).

In addition, even if the court does accept a scientific opinion from the expert, it may rule against the expert's recommendations because other facts that came out during the trial, possibly concealed from the expert, make it improbable that the expert's information is prevelant or valid. Usually the trier of fact does not totally neglect the expert's information, but rather exerts that the expert has not carried their burden of proof to the degree stipulated by law (Cook, 1964). In civil cases, the law requires that the preponderance of evidence be demonstrated, while in criminal law the data must be shown to be beyond a shadow of doubt. Furthermore, in regard to child welfare cases, the hearing officer is an advocate for the child and may elect to recommend a course of action different from the positions recommended by any of the parties involved. This can lead to some creative and unanticipated resolutions.

Whatever the outcome, expert witnesses should remember that it is their charge to function as advocates of the facts as they have perceived them, and to present this information in as clear and meaningful terms as possible. The rest is out of their hands and the charge of the court system.

The Written Court Report

Just as in the expert's textimony, the fundamental purpose of the expert's written report is to provide useful and relevant information to the court to assist the legal system in making an informed judicial decision. When expert witnesses provide testimony along with their submitted written report, they can expound upon any aspects of the document that are unclear and answer directed questions that may be elicited. However, when the expert does not testify and is represented only by a written court report, that document must be comprehensive in scope and balanced with concise and forthright content. The following information, suggestions, and considerations are presented to assist the school psychologist in constructing and submitting a written court report.

The comprehensive report. In their day-to-day practice, most school psychologists are involved in multidisciplinary team approaches to assessment, decision making, program planning, and recommendation implementation. The team approach as specified in the Individuals with Disabilities Education Act (IDEA), formerly known as the Education for All Handicapped Children Act of 1975 (Federal Register, 1977), provides protection and an assurance of checks and balances by drawing on a variety of perspectives from different disciplines. In addition, when there is a multidisciplinary team approach the individual written reports are seen as fragments of information that converge to give an overall comprehensive picture of the individual client. But in many civil and criminal law cases, the psychologist does not have the luxury of the multidisciplinary team assessment and resulting written documentation. In fact, in many such cases the psychologist's written report is entered into court as the only input from an expert mental health practitioner. This can greatly increase the potential impact and importance of the psychologist's report and the responsibility of the school psychologist in court interventions.

The court report versus the traditional psychological report. There are as many acceptable court report writing formats and styles as there are traditional psychological report writing formats and styles. It is of utmost importance that the written report be tailored to the individual client and case, rather than attempting to fit the client to a predetermined model of reporting.

The comprehensive court report utilizes most of the typical sections of the traditional report with the addition of several distinctive features. The first distinctive feature of a good court report is that it clearly identifies the reason for referral by specifying in detail what questions the report will address. After specifying the questions to be addressed, the court report should delineate the purpose and scope of the evaluation. This sets the structure for the intervention which is conducted and the format for how data will be presented in the report.

Another important feature of the court report is the review of relevant history and current data. The word *relevant* should be highlighted, because as a comprehensive report the psychologist should exhaustively search for relevant background information but not pad the document with unnecessary information. It is considered unethical to provide the court with interesting or unusual information that is not relevant to the court's disposition. A client's right to confidentiality should be protected even when authorization to release information has been granted; thus information released should be directly pertinent to the case. Since this report may be the only professional opinion entered into the court record, a complete psychosocial history should be taken but again only with pertinent information presented. This section should carefully list the sources and informants consulted to gather the background information.

The next section of the court report usually contains the clinical interview and notes about the client's behavior during the evaluation. The distinction between this section and that usually reported in a school psychological report is the additional reporting of a client's mental status. A mental status examination consists of assessing the client's dress, grooming, and general appearance, degree of cooperation; emotional responses, affect and mood; thought content; orientation as to person, place, and time; memory and attention; language usage; and the professional's general impression of the client.

The assessment section should use as comprehensive a battery of formalized assessment instruments as are necessary to obtain the appropriate data without overevaluation. In addition, functional assessment data including relevant progress monitoring data can be useful.

The final and most important section of the written court report is the summary and recommendations. It is most important because it is often the first, and sometimes only, section thoroughly read. The whole report should be written to support and focus on this section. The summary should synthesize and converge all the relevant information into a concise and forthright presentation. The recommendations should answer each of the questions posed in the reason for referral section in terms of conclusions, opinions, and specific recommendations.

The evaluation report versus the data report. When a psychologist is retained by the judicial system the court is asking for an expert opinion. A data report that clerically reports uninterpreted data is of little use and does not meet the needs of the legal system. The expectations of a professional court report is that it will make specific recommendations that will answer the referral questions. The court demands an expert's professional opinions, inferences, and recommendations, and that is what school psychologists should include in their evaluation report.

Technical specificity. It is very helpful to know in advance the target audience for the written court report. In most instances court reports should be straightforward and free of technical jargon. There are situations, however, such as when there is a nonjury trial and the judge is particularly sophisticated in psychological testimony and terminology, that it is appropriate to present data in a more technical report-writing style. Even so, the psychologist should keep in mind that any good written report should meet the criterion of communicating well.

Clarity through graphs and charts. To aid in communicating psychological data to the court in the written report, the visual impact of graphs and charts can be very helpful. This means of presentation can be especially advantageous in comparing the referred client to a normative population and to demonstrate changes over time through, for example, progress-monitoring data.

Submitting the written court report. To alleviate any difficulties or misunderstandings, the intended recipients of the written court report should be clarified and stipulated prior to expert's initiating their evaluation of a client. In addition, it is ethically responsible for the psychologist to notify the client prior to the evaluation how the information obtained during the evaluation will be utilized and what parties will be exposed to it. After the evaluation has been completed and the report written, it should then be delivered to the specified recipients in keeping with the timetable previously established.

SUMMARY

Optimal courtroom performance is accomplished through the combination of implementing competent best practices in the delivery of all pretrial professional services and thoroughly preparing testimony material prior to taking the witness stand. Diligent pretrial preparation greatly alleviates courtroom stress, can keep the school psychologist from getting beat up in the courtroom, is ethically responsible in terms of the client's welfare, and can have a potentially positive impact on the esteem others hold for the profession of psychology.

The school psychologist assists the court in two major ways: through the delivery of verbal testimony and through the creation of tangible evidence for the court to consider (e.g., psychological reports, videotapes, work samples, charts of progress-monitoring). The fundamental purpose of verbal testimony and tangible evidence is to provide useful and relevant information to the court to help the legal system in making an informed judicial decision. These legal decisions not only impact the individual case being tried but can also generalize to define the work environment for all school psychologists practicing in an educational setting.

This chapter discussed (a) the process of pretrial preparation (gathering and disseminating of information, utilizing files and constructing a face sheet, obtaining legal consultation and preparation, presenting professional credentials effectively, and acquiring courtroom conditioning); (b) the direct examination procedure (the adversarial process, providing appropriate advocacy, responding to questions effectively, and presenting limitations and contradictory data); (c) surviving and making points through the cross-examination (preparing for the attack, understanding common traps, and investigating expert witness strategies); and (d) other considerations (fee considerations and tolerating unexpected outcomes). In addition, the written court report was examined and the differences between a court report and a traditional psychological report written for school purposes were delineated.

ANNOTATED BIBLIOGRAPHY

Brodsky, S. L. (1991). *Testifying in court: Guidelines and maxims for the expert witness.* Washington, DC: American Psychological Association.
Brodsky's book concentrates on educating the psychologist on the cross-examination process. Brodsky highlights the questions often asked, the power and control gambits attorneys use, the lines of questions, the nonverbal parrying, and the special limitations of courtroom rules. The basic lessons are directed at allowing the witnesses to comply with the oath of honesty, to be responsive to the questions asked and to the witness role, and to be able to defend themselves, their opinions, and their integrity. This book is intended to do one thing: to present a way of thinking about court testimony and to offer a series of choices and alternatives for thinking about testifying in court.

Schwitzgebel, R. L., & Schwitzgebel, R. K. (1980). *Law and psychological practice.* New York: Wiley.
The purpose of this book is to lead human service professionals and interested clients through the unfamiliar territory of law and psychological practice. Included in the book is a wide variety of helpful information for the school psychologist, including chapters on patients' rights, punishment, psychological testing, school law, confidential communications, malpractice, and many others. Another helpful aspect of this book is the inclusion of a multitude of appendices, including a sample contingency contract for therapy, an intervention contract, a behavior management program consent form, a consent form for a minor to participate in research, and many more.

Ziskin, J. (1975). *Coping with psychiatric and psychological testimony* (2nd ed.). Beverly Hills, CA: Law and Psychology Press.
Ziskin's book is useful for school psychologists because it reveals how their testimony can be potentially torn down. The book is written to provide lawyers with the tools they need to bar psychiatric or psychological testimony in most cases and to dilute or destroy its effect in those cases where it is admitted through utilizing scientific literature to have evidence not admitted or to systematically and methodically reduce the credibility of psychiatrists and psychologists.

Best Practices in APA Policy and Advocacy for School Psychology Practice

Ronda C. Talley
American Psychological Association
Center for Psychology in Schools and Education

OVERVIEW

Policy and *advocacy* may sound like terms that have relevance only for the Washington lobbyist or the state association legislative chair. However, nothing could be further from the truth. Whether it is realized or not, each psychologist engages in policy and/or advocacy activities every single day, whether by design or default. The development, implementation, or expression of policy and advocacy take place at the local level through such simple acts as offering an opinion based on scientific data, interpreting an assessment report according to state or district guidelines, or assisting a parent or guardian to access needed services. Concomitantly, policy and advocacy initiatives occur at the state or federal levels through the expression of positions which inform relevant decision makers in those arenas. Psychologists are needed at each of these levels to articulate considered and consistent positions and to coordinate activities that emphasize psychology's expertise in providing solutions to the issues facing America's schools and its students in this century and beyond.

Why should policy and advocacy initiatives be a concern for the school psychology practitioner? One compelling reason is that these issues affect the daily practice of psychology at the local level. Policy positions developed at the district, state, or national levels may have a profound influence on *what* psychologists are allowed to do and *how* it may be done.

An example of this need for coordination in advocacy activities recently occurred at the national level but has implications for state and local practice. In this case, when the Elementary and Secondary Education Act was before the U.S. Congress for reauthorization, the American Psychological Association (APA) suggested inclusion of a definition for "supervisor of pupil services" which would allow years of experience as a school psychologist to count in lieu of teaching experience for that administrative credential. If this addition is retained in the final draft of the legislation, which has been renamed the Improving America's Schools Act of 1994 (IASA), then school psychologists in each state could use this federal model to advocate for school psychological practice experience to qualify them for the supervisory credential. This is important because in many states, school psychologists are not allowed to move into supervisory positions unless they have a specific number of years of teaching experience. While some states have formulated advocacy plans to remedy this situation, parallel activities at the federal level may help support all states' efforts. This change would open up a career ladder for school psychologists and allow them to supervise their own school psychology programs in states where currently they may be prohibited from doing so by the teaching experience requirement. This example illustrates that the school psychology practitioner should be concerned about policy and advocacy because *the psychologist's employment and ability to function as a professional is affected.*

Secondly, psychologists have a tremendous range and breadth of knowledge and experience which should be brought to bear on current social issues. For example, psychologists are critical experts on issues such as violence affecting children and youth, the impact of television and other media on youngsters, public health issues in the schools, and education reform. Psychologists address these concerns and others by assisting in the development of school-based or school-linked prevention and intervention activities, including leading services integration activities, initiating programs to help students successfully negotiate challenging developmental hurdles (i.e., preschool development ad middle school transition), and developing community/family outreach and involvement components. Psychologists' advocacy in social issues serves to inform the larger school community and public, including policy makers. It also provides a scientific foundation to the development, implementation, and evaluation of programs designed to ameliorate societal problems related to the education of America's youth. Thus, the school psychology practitioner should be concerned about policy and advocacy issues because *the psychologist has* *something to give back to society and society needs the skills of psychologists.*

While there are many other reasons, such as our relevance to society, our identity, and our employment and practice, for psychologists to be actively involved in policy and advocacy activities, an overriding and compelling reason for our involvement is the *opportunity to positively influence the futures of children.* Psychologists, as professionals and often parents, are personal stakeholders in the mission of effecting positive social change. The lives of children can be enhanced through policy and advocacy efforts. As psychologists, we must act proactively, responsibly, and skillfully in leading advocacy efforts which contribute to the positive development of the nation's most precious resource, its children.

In this chapter, issues related to policy and advocacy for school psychology practice will be explored. Four prominent reform movements and their implications for psychology will be discussed and examples of advocacy efforts for each movement will be presented. It is hoped that the illustrations of advocacy activities at the federal level will provide examples or blueprints of action for initiatives which may also occur at state and local levels.

BASIC CONSIDERATIONS

Getting Started

While some professionals think of the *activities* initiated to address policy development and advocacy concerns as a central focus, they are really one of the last steps to be implemented in the process. As noted by Johnson (1994), "important changes do not occur at the margins, but rather when the social structures in which we live our lives are re-made" (p. 117). Therefore, before engaging in policy and advocacy initiatives, the psychologist or group should consider its characteristics, assumptions, philosophies, and goals. These should be clearly articulated in an organizational description and mission statement. The following is an example of such an organization description and mission statement by the Psychology in the Schools Program of the American Psychological Association (APA).

APA Organizational Statement

> The American Psychological Association (APA) is the largest scientific and professional organization representing psychology in the United States and is the world's largest association of psychologists. APA's membership includes more than 118,000 clinicians, researchers, educators, consultants, and students. Through its divisions in 48 subfields of psychology and affiliations with 57 state and Canadian provincial psychological associations, APA has worked for more than 100 years to advance psychology as a science, as a profession, and as a means of promoting human welfare. APA publishes 21 psychological journals, 7 secondary journals, *Clinicians Research Digest*, and numerous books and monographs. APA headquarters operations and programs are managed through the Executive Office, the Office of Publications, and Communications, and four Directorates — Education, Practice, Public Interest, and Science.

Psychology in the Schools Program Mission Statement

> The Psychology in the Schools Program of the American Psychological Association is a point within the association where issues pertaining to the practice of psychology in school settings are addressed. Furthermore, since the majority of psychological practice in schools is conducted by school psychologists, this group represents a key constituency for the program. In addition, the issues faced by school psychologists who practice in hospitals, mental health centers, agencies, universities, or other settings, including private practice, are areas of concentration. Th program engages in political and professional advocacy and policy development in response to both guild ad professional practice issues that face practicing psychologists who seek to provide quality services to children, youth, families, school and agency staff, and systems (Talley, 1992).

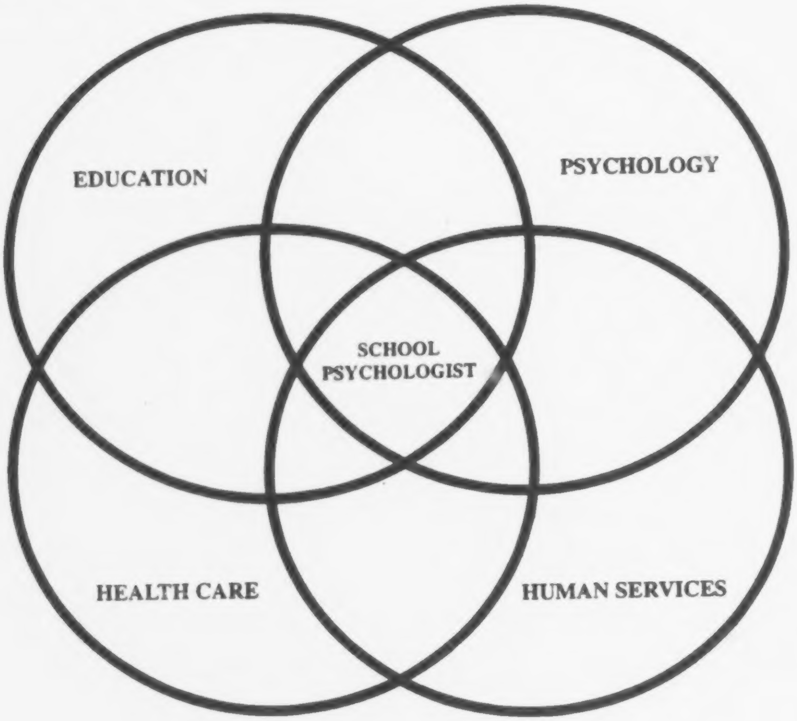
After these characteristics are specified and advocacy goals are articulated, work then focuses on development of a formal or informal strategic plan for their accomplishment. For example, with the APA Psychology in the Schools Program, a strategic plan was written (Talley, 1992) and disseminated to relevant stakeholders for review and feedback. The plan addressed all major areas of program responsibility in relation to the identified goals and specified activities for each area. Actions formed the last area of the plan and emanated from the program assumptions and goals. For additional projects to be considered for action, they had to prove pertinent to the identified goal areas and complementary to existing program activities.

Considering the Issues

When considering which policy and advocacy goals should be considered in developing a strategic plan, planners must explore the major issues affecting practice. In this section, four prominent social issues which may dramatically impact school practice are highlighted (see Figure 1). Following a discussion of the four major reform issues that influence American education, examples of advocacy efforts implemented in each area are presented.

In American society today, there is a massive convergence of social issues which affect the schools. The most well known of these for educators is, of course, the education reform movement. This movement embodies both the eight national education goals and a wider array of structural and procedural

FIGURE 1. Reform movements of the 1990s.



issues pertaining to the way schools work and the definition of their mission.

A parallel and sometimes overlapping reform movement may be found in the health care system. With many schools throughout the nation adding school health clinics to their list of basic services, it is unclear where the delivery of health promotion as well as mental health services fits into the new service delivery paradigms

A third and less widely discussed social movement is occurring in human services. The human services reform movement has two parts: services integration and welfare reform. While school psychologists are not consistently involved in welfare reform issues, the services integration movement appears to be sweeping the nation. Schools are seeking personnel with the consultative and processing skills to lead teams who integrate services between schools and communities.

The fourth reform movement impacting school psychologists is primarily an internal one: Psychology is changing. There is dialogue and debate concerning, to name a few issues, the minimal training required for practice, the redefinition of specialties, the training of psychologists who can prescribe medication, and appropriate credentialling bodies for training programs and individuals. Qualitatively, it seems a time of bold visions and new opportunities. Advocacy efforts associated with this and the other three reform movements will be considered next.

Education Reform

The national education goals have been promoted as a standard for American education. However, the education reform movement as embodied by the goals actually constitutes a broad pattern for comprehensive services for children and adults that addresses health, social needs, mental health, and development as well as education. Whereas American education traditionally has occurred within the confines of the school building, education reform cannot be achieved without a coordinated, integrated, and interdisciplinary effort that also includes parents, social and health agencies, and communities. In fact, service delivery within education reform and the proposed health care reform may share many mechanisms and objectives. These two reform movements, sometimes overlapping and sometimes parallel, may provide psychology with an unprecedented opportunity to redefine psychological service delivery for the 21st century.

However, psychology has been conspicuously absent in policy and program development for educational reform. Short and Talley (1993) describe this as an important reason for the lack of progress in education reform initiatives. They note that although psychological theory and research underlie much of educational practice, education policy and the educational literature seldom cite psychological contributions to the improvement of education. Frank Farley, Past-President of the APA, cogently noted this disparity:

> In my view, a central reason for the slow progress in reform is the relative absence of psychology in the equation for educational change. The principle target for education reform should be the *minds of kids*. If the minds of kids are to the bull's eye, then we're not going to much improve education. We will simply be rearranging the deck chairs on the Titanic. No discipline is more sure-footed on the mindscape of kids than psychology. Psychology is the core science of mind, and without psychology's signature on the blueprint of education reform, reform will fail. Therefore, it is imperative that we advocate for a *psychology of education reform*. (Farley, 1993, p. 15)

Health Care Reform

America is witnessing a clear change in direction in health care and education policy (Short, 1993). Of the numerous pieces of health care reform legislation introduced in Congress, only the Health Security Act of 1994 proposed by President Clinton contained a specific section devoted to schools. In Title III, Subtitle G, two dimensions of school health care were addressed: comprehensive school health education and school-related health services. Health, prevention, and education rather than disease, intervention, and mental health were emphasized. This is one sign that, within the health care reform movement, emphasis on specialized care for clinical populations is yielding to a more preventive, comprehensive orientation that addresses specific social and health problems such as intentional injury and substance abuse. Schools and educational agencies are primary settings for the delivery of services with this orientation, and psychologists are uniquely prepared to provide comprehensive preventive services in schools and communities.

As health care reform initiatives are considered at the state and federal levels, schools will no longer be in the exclusive purview of education. Psychologists who practice in schools need to prepare for a new reality in terms of school-based health service provision and would do well to consider how their services will be viewed and valued. Indeed, legislation may provide a challenge and an opportunity to recast psychological service delivery to children and youth (Talley & Short, 1994a, 1994b).

Human Services Reform: Services Integration

While education and health reform have been highly touted in the last few years, a third revolution — in the human services area — has been brewing. This new movement, called *services integration*, has provided an opportunity for psychology to position itself for the delivery of services across multiple settings in a teaming fashion with other health service providers. Services integration is defined by the National Alliance of Pupil Services Organizations as "the process by which a range of education, health, and psycho-social services are delivered in a coordinated way to individuals and family systems" (1992b).

Current legislation defining comprehensive school health services emphasizes the education of the individual student in the school and classroom. However, the prevention of many childhood health problems requires a much broader and more coordinated educative focus, in other words, a services integration approach. Failure to address behaviors and characteristics of parents, peers, and communities minimizes the potential effectiveness of school-based educational interventions. Because parents, peers, and communities are critically important to the development, prevention, and treatment of the problems addressed in legislation, involvement of these groups in health education is crucial. The skills and expertise of psychologists provide a productive tool for pulling together various constituencies for effective planning and services for children.

Within the services integration movement, psychologists will be impacted in four ways. In the area of training, psychologists will need greater breadth and flexibility, with opportunities for training as team members with other health service professionals. Psychologists will be asked to assume leadership roles within integrated services programs providing program administration ad supervision, building collaborative teams, and facilitating planned change in the direction of more integrated services. Practitioners will be able to exercise greater flexibility in the range of activities with which they engage and not be constrained in regard to funding source and eligibility considerations. And finally, psychological research on the efficacy of integrated service delivery approaches for children and families represents a unique contribution for psychology.

The Reform of Psychology

As mentioned earlier, a number of changes are either occurring or being considered within America psychology. With the convergence of these major issues, psychology may find an opportunity to consider new ways of viewing the profession and what constitutes psychological service delivery. For example, for services integration initiatives to be successful, psychologists increasingly find themselves working in teams of human service providers across a variety of disciplines with services occurring both on and off school grounds. Increasing numbers of psychologists may choose to acquire additional training in order to prescribe medications as this idea becomes more accepted both within the profession and in society. Both education reform and health care reform with their many overlapping features, will call for new and creative ways for psychologists to work with teachers, administrators, parents, agencies, and the community. The reform of the profession of psychology will challenge psychologists to be consumer oriented and responsive to system needs. Agencies, associations, and credentialling bodies must also be responsive to changing consumer demands. Psychologists with the social, process, and content skills needed in these changing paradigms will thrive.

BEST PRACTICES

In beginning a program of policy development and advocacy, it may be useful to examine a range of strategies and activities successfully implemented by other groups. The following section treats each of the four areas previously discussed and highlights activities which the American Psychological Association has initiated to address social reforms on behalf of American psychology.

Education Reform

Legislative/regulatory advocacy. In 1993, APA's Education Directorate formed the Schools Advisory Group in Education (SAGE) to promote the role of psychology in improving American schools and education in the national legislative and policy agenda, including applications, practice, training, and research. SAGE was designed to address all major education and education-related legislation and policy, including all major social issues impacting education: education and education reform; schools, education, and prevention in health care reform; educational technology; schools and education in welfare reform; education and training of psychologists in schools and education; and the role of schools in crime and judicial legislation. Most recently, SAGE has provided recommendations to Congress promoting psychology's role in Goals 2000: The Educate America Act, the Improving America's Schools Act, and recent crime and safe schools legislation.

APA Task Force on Psychological Principles and School Psychological Services in Education Reform (TFER). The TFER was established in 1994 to promote psychology's role in the education reform movement; to articulate psychology's contribution to children, families, and systems in advancing the national education goals; and to develop model psychological service delivery systems to promote these goals in states and local school systems. The Task Force was charged with developing a proposal for an APA-wide action plan to promote the role of psychology and psychologists in education reform. In accomplishing their mission, the Task Force examined models for education reform and school change and specified the roles psychology and psychologists can play in influencing the legislation to be developed and in designing and providing services to support reform objectives.

APA/NEA collaboration. The APA/NEA (National Education Association) collaboration was begun in 1991 as a means to promote a number of psychological and educational issues (" APA, NEA work ..." 1994). The collaboration, formalized in a December 1993 meeting between the two associations, continues to promote the common concerns and mutual interests of both groups. The goal is the establishment of collaborative mechanisms between the two groups with the intention of culminating in the joint approval of a formal memorandum of collaboration. The American Psychological Association brings to the collaboration expertise in psychological issues related to the education and health of individuals and systems as well as information pertaining to the practice of psychology in schools. The National Education Association brings to the collaboration its representation of over 2.2 million teachers, psychologists, and other education personnel and its expertise on critical issues in American education. The APA/NEA collaboration promotes the common agendas of both associations through the development of joint policy/position statements; publications, legislative/lobbying activities; research, training, and practice activities; and positions on state and local collective bargaining efforts.

APA/National Education Goals Panel collaboration. The APA has played a leadership role in representing psychology to the nation's governors, the President's education staff, and education members of Congress. This group, as represented by the National Education Goals Panel (NEGP), invited APA to draft its definitional paper on Goal Seven of the national education goals, commonly referred to as the "safe schools" goal. The NEGP is a bipartisan group comprised of governors, members of the Clinton administration, and members of Congress which has as its mission "to build a nation of learners" (NEGP, 1993).

APA/NAPSO collaboration. In addition, the NEGP and the National Alliance of Pupil Services Organization (NAPSO), of which APA is a member, sponsored a national conference on Goal Seven of the national education goals in October 1994. The conference, targeted to education policy makers and pupil services practitioners, focused on solutions to school violence, substance abuse, and highlighted the creation of environments conducive to learning. The conference offered a unique opportunity to present the case for pupil services, including school psychology, as an essential ingredient in addressing educational, health, and safety issues pertaining to America's children and youth. The NAPSO is a coalition of 23 national professional organizations whose members provide "a variety of primary, preventive, developmental, remedial, and supportive services which are required to assist children and youth to benefit fully from their education" (NAPSO, 1992).

Health Care and Human Services Reform

Schools as health service delivery sites work group. This group was established in 1993 and charged with producing a report on schools as health service delivery sites in national health reform. Specific areas addressed in the report include (a) a historical perspective on the role of schools as settings for the provision of primary health care, (b) clarification of the definition of a health care setting and rationale regarding how the schools and/or school-based clinics meet these criteria; (c) clarification of the schools as appropriate health service delivery settings for the psychology internship; (d) identification of legislative and educational structures that support or limit the roles of schools as health care provider settings; (e) an examination of existing and potential roles for psychologists in the public school health care delivery system; (f) identification of models of comprehensive and coordinated services for children that currently exist in public schools with an analysis of evaluation data regarding their effectiveness in meeting the mental health needs of children; (g) an examination of reimbursement issues for psychologists in school settings; and (h) a description of how psychologists in schools provide an essential function in the delivery, coordination, and integration of a variety of children's mental health services. After completion, the report will be used to design a number of additional advocacy initiatives around health service delivery in schools and the roles which school psychologists have in this process.

APA Task Force on Comprehensive and Coordinated Psychological Services for Children Age 0–10 (TFCCPS). The TFCCPS was established in 1991 and charged with assessing the current array of services available to met the psychological and mental health needs of children from birth through age 10 with particular emphasis placed on the delivery of services within school settings. Further, after identification of the current service delivery needs, the TFCCPS was charged with analyzing available resources, comparing service needs with resources to determine gaps in service delivery, and recommending how these gaps should be addressed to provide a comprehensive and coordinated array of services to meet the psychological and mental health needs of children. In fulfilling its charge, the TFCCPS built on the work of many leaders, including Melville and Blank (1991) and NAPSO (1993) to produce a report entitled *Comprehensive and Coordinated Psychological Services for Children: A Call for Service Integration* (Paavola et al., 1995), a two-page fact sheet on "Children's Mental Health Needs: Reform of the Current System" (1993), a book prospectus on service integration, and a draft "Children's Agenda" for APA. Additionally, in the spring of 1993, the TFCCPS hosted a meeting of over 50 children's issues groups to discuss psychology's contributions to and advocacy in this area.

The Reform of Psychology

Leadership development. To establish a dialogue with school psychology leaders in the field and to provide key leaders with an opportunity to discuss reform issues in their states and at the federal level, the APA and the Administrators of School Psychological Services (ASPS) group of the Division of School Psychology joined forces in 1994 to offer the first Institute for Administrators of School Psychological Services. The Institute was held in conjunction with the APA convention and carried the theme "Advocacy for School Psychological Services Practice: Challenges for the Year 2000." The superintendent of the Los Angeles Unified School District, Sidney A. Thompson, and Dr. Cindy Carlson, President of the APA's Division of School Psychology, were keynote speakers. In addition, sessions were offered on the following topics: school psychologists in education and health care reform, school violence and crisis planning, services integration and interagency collaboration, school psychological services program evaluation and student outcomes, and continuing professional development for changing service needs.

Networking. In 1993, APA christened its electronic communications system, the School Psychology Leaders Network (SPLN). Leaders in the field of school psychology were added to this electronic mail network and receive regular updates from the APA Center for Psychology in Schools and Education on legislative progress, new publications, pertinent announcements from the federal government, and other items of interest.

In both 1993 and 1994, the APA Center for Psychology in Schools and Education produced the *APA Leaders in School Psychology Directory* ("New Directory," 1994). The *Directory* lists all school psychology leaders who serve the association or work with the Division of School Psychology. Division task force chairs are also included. The following information is available for each person in the *Directory;* name, title, mailing address, telephone and fax numbers, two primary ares of expertise, and major professional affiliations and offices. Copies are available free of charge.

Print advocacy. In December 1993, the APA announced the publication of two new documents related to school psychology practice. The first document, *Guide for the School Psychologist: A System for the Promotion of Diversified Psychological Services in Schools* ("Guide for," 1993), is designed to aid practicing school psychologists in providing information on the myriad of services which they deliver. The second publication, *Delivery of Comprehensive School Psychological Services: An Educator's Guide* (Jackson et al., 1993), explains school psychologists and their work to school administrators.

In addition to formal reports, APA has produced numerous articles and other publications related to reforms occurring in psychology and psychological practice (APA, 1994a, 1994b; De Angelis, 1994; de Groot, 1994a, 1994b) as well as articles to address general advocacy issues (Allen, 1993; *Federal Advocacy Handbook*, 1993; *Psychology in the Public Interest*, 1992). APA affiliates, such as the Pennsylvania Psychological Association (1992), have also been active in advocacy issues through the publication of political handbooks.

Division of school psychology. The APA Division of School Psychology has also shown leadership in the reform of psychology through publications (Carlson, 1994; DeMers, 1993), and the establishment of task forces to study reform issues as they specifically apply to school psychology. For example, the Division has established a group to review the APA draft document, *Learner-Centered Principles for School Redesign and Reform* (1993), develop a report on psychopharmacology and children, and redraft the school psychology specialty guidelines.

SUMMARY

Policy and advocacy in school psychology is one of the most challenging and exciting areas of professional practice. It requires patience, determination, knowledge, social skills, negotiation abilities, key contacts, and time. And, of course, it requires that one views the cause as significant in terms of potential benefit to a long-range program of political advocacy. Policy and advocacy initiatives must engender a sense of focus and dedication which allow the advocate to set aside other peripheral concerns and implement a plan to accomplish a set of recognized and valued goals.

School psychologists have a vested interest in influencing policy and advocacy positions. They should be key players in the reform movements of the 1990s: education reform, health care reform, human services reform (including services integration), and the reform of psychology. Initiatives in this area affect school psychologists' practice and employment, their relevance and professional identity, and, most importantly, the lives of children and youth. Because psychologists have the scientific knowledge and technical expertise to inform policy decisions and to lay the foundation for well researched advocacy proposals, it is a critical part of their responsibility to the profession and to society to use their training and experience to positively shape social policy. Each psychologist should seek ways through which this challenge may be met.

ACKNOWLEDGEMENT

The author wishes to acknowledge her collaboration with Dr. Rick Jay Short, Assistant Executive Director for Education in the APA Education Directorate, on many of the school psychology advocacy efforts described in this article. Dr. Short's equal contribution to these is greatly appreciated and fully acknowledged.

ANNOTATED BIBLIOGRAPHY

American Psychological Association. (1994). *Psychology's role in health care: Psychological services for the 21st century*. (Packet available from the American Psychological Association, 750 First Street, NE, Washington, DC 2002-4242.)

The American Psychological Association has developed a packet of individual documents on a variety of health care topics which are designed to inform the public about what psychology has to contribute to health care. Individual flyers with the following titles are included: improving America's schools, preventing youth violence, promoting women's health, making work places safer and more productive, educating and training the next generation of psychologists, mental health services cut overall health costs, psychological services address a range of health concerns, psychological research: vital to health care reform, and psychological services: integral to a new health care system. The packet's overall theme focuses on how psychologists promote health services, and save health care dollars. A limited number of packets are available free of charge.

Jackson, J. H., Balinky, J. L., Lambert, N. M., Oakland, T. D., De Mers, S. T., Alpert, J. L., Reynolds, C. R., & Talley, R. C. (1993). *Delivery of comprehensive school psychological services: An educator's guide*. Washington, DC: American Psychological Association.

This booklet, referred to as "the educator's guide," was produced by the APA Task Force for Psychology in the Schools and is now in its second printing. The publication, directed to school administrators, attempts to provide basic information on what a school psychological services program should look like at the local district level. The first chapter, "Your School Psychologist," offers information on how psychologists work and with whom they do their work. It also addresses what type of services psychologists provide: support of school-wide or district-wide programs and services to individual students, groups, and families. Next, "Planning and Developing a School Psychological Services Program" provides an outline with which a district can build or refine a program. The third chapter, "Enhancement of School and District Goals Through Use of School Psychological Services," addresses general contributions of school psychologists to the enhancement of school goals: It also offers a section on research and program evaluation as they are used to support school goals. The final chapter, "Legal, Ethical, and Professional Issues in the Delivery of Psychological Services in Schools," targets litigation and legislation that affects school psychologists in schools. Copies of this document are available for $10.

Psychology in the public interest: A psychologist's guide to advocacy. (1992). (Available from the Public Policy Office, American Psychological Association, 750 First Street, NE, Washington, DC 20002-4242.)

The *Psychologist's Guide to Advocacy* is a brief primer on the legislative process. Its topics are organized under three major headings: APA advocacy for psychology, a short course in the legislative process, and effective communications. Within these major areas, topics include understanding the legislative process, selecting committees and subcommittees to target for advocacy efforts, determining how a legislator decides to vote, and examining the regulatory process. A separate section provides details on identifying and locating our legislators, understanding the role of Congressional staff, writing a constituent letter, making a constituent telephone call, meeting with your legislator, and inviting your legislator to visit. Copies of the document are available free of charge from the APA Public Policy Office.

Short, R. J. , & Talley, R. C. (1993). *A psychology of education reform*. Paper prepared at the request of the APA Board of Educational Affairs. (Available from the American Psychological Association, 705 First Street, NE, Washington, DC 20002-4242.)

This document was developed to inform psychologists of the importance of being involved in education issues. It begins by highlighting how education reform extends far beyond the schoolhouse and moves to focus on why psychology is important to eduction reform. The article documents the importance of psychology to education by addressing each of the national education goals and provides examples of how psychology im-

pacts each goal. The document concludes by stating the case for why education reform is important to school psychology: It affects our practice, our relevance and identity, our children, and our employment. Copies are available free of charge.

Focus on Systems

Best Practices in Fostering School/Community Relationships

Susan M. Sheridan
University of Utah

> *Schools cannot provide all the needed resources for educating children today, nor can communities themselves — both must begin to collaborate to improve the schools of our nation.*
>
> National Association of State
> Boards of Education, 1992

Today's youth soon will be responsible for sustaining America's work force, for enhancing the economic climate of the country, and for enriching the social resources of society. Our future in large part rests on the ability of youth to fulfill the tasks necessary to support the economic, political, and social structures of our country. To ensure that students are equipped with skills to carry out this daunting responsibility, communities *must* become actively involved in education. This is not simply a "nice idea" — it is a necessity.

Communities have a myriad of resources. A vast number of assets is available outside of the school walls, and it is becoming more and more important to tap these resources and establish meaningful and productive school/community partnerships. The purposes of this chapter are to provide an overview of school/community partnerships; identify basic considerations for establishing effective relations; and review various models of school/community partnerships.

OVERVIEW

Definition of School/Community "Partnerships"

Over time, the relationship between schools and communities has changed. In the early days of formal education, the "social and physical distances between teachers and the community" were minimal (Tangri & Moles, 1987, p. 519). As schools adopted a central educational responsibility in society, however, the notion that schools should be separate and isolated from the community became rigidly reinforced. This isolation from the community has contributed to several problems faced by schools, such as limited resources, lack of community confidence in schools, and little communication. The barriers between schools and communities must be overcome, and the most fruitful way to begin this process is to conceptualize the relationship as a partnership.

Webster (1981) defines "partnerships" and "partner" as the "state of being a partner . . . one who shares" (p. 829). A partnership assumes a close, cooperative relationship wherein all parties (students, teachers, and community representatives) have specific and joint rights and responsibilities. The objectives of educational partnerships include (a) pooling and sharing of talents, resources, and efforts to achieve a commonly defined mission in the education of students; (b) empowering educational personnel to access, refine, and/or develop new, creative approaches; (c) developing and refining professional skills through the exchange of ideas, knowledge, and expertise; and (d) enhancing educational services to *all* students (Welch & Sheridan, in press). In this framework, all participants in the partnership benefit.

Various partnerships are possible in educational environments, ranging from student–student cooperative structures to home–school partnerships to community-based instruction and training. A pragmatic schema for conceptualizing various forms of partnerships appears in Figure 1. This chapter is concerned with the broadest level of partnership cutting across the greatest number of settings, individuals, and functions: that of school/community partnerships.

Benefits of School/Community Partnerships

Several advantages lie in developing and strengthening the relationship between schools and communities. Community agencies and businesses often can provide a unique educational experience that is unavailable in traditional, isolated school buildings. Community involvement can increase students' awareness of means by which to contribute to society. It can enhance students' understanding of citizenship and social commitment. It can also help develop such important values as respect for others and civic responsibility (National Association of State Boards of Education, 1992). Work experiences, vol-

unteer or other community service practices, and field-based learning opportunities also provide effective, hands-on educational possibilities beyond the classroom walls.

Besides these obvious immediate benefits to students, productive partnerships also provide advantages to communities and schools. An important benefit is the improvement of skills in the labor pool from which businesses and communities will draw their work force. Community and business participants often report a boost in morale from their involvement with students and a renewed sense of pride and value in their own work (Tangri & Moles, 1987).

Schools also derive benefits from active school/community partnerships. Most obvious is the time, expertise, and equipment that businesses and the community donate to educational programs. Direct assistance in the form of personnel development, food assistance, management, and purchasing also have become available to schools through community involvement. Schools involved with successful programs also report lower absenteeism, truancy, and dropout rates (Bucknam, 1976).

When teachers are actively involved in the development or implementation of school/community programs, they benefit through career exploration, expanded roles, and increased involvement with the community. Ideally, teachers receive formal training or internships to enhance their position as a community liaison.

CONSIDERATIONS

Perhaps more important than any other consideration, it is essential that efforts to build, strengthen, and maintain school/community relationships be well thought out and planned. It is not sufficient that school and community persons have good intentions to forge a working partnership; rather, they must have a clear vision of what the partnership will achieve and an operational plan for accomplishing that mission.

A report of the National Association of State Boards of Education (1992) outlined several principles of community involvement. The first suggested that programs be well managed and skillfully organized. This requires the development of an appropriate and adequate management plan, which should include specific details about activities (what?), responsibilities (who?), time lines (when?), locations (where?), and procedures (how?).

Second, effective school/community partnerships are flexible. The organization and implementation of the management plan must be based on the needs of the school involved and the local community. Each school, community, and school/community interaction is unique; therefore, the goals, objectives, and program guidelines must be specific to local issues. Further, aspects of the community (e.g., socioeconomic status, size, nature of businesses and organizations, community strengths) must be considered, to realize maximum benefits.

A third characteristic of successful school/community partnerships is an adequate time commitment. Quality relationships require a significant amount of time to develop, strengthen, rework, and evaluate. Partnerships will not form overnight and will not maintain themselves without concerted effort and a long-term commitment. Likewise, the needs and resources of local schools and communities will change over time. Therefore, the partnership requires continued creativity and reconceptualization of the means by which its efforts can produce the best results.

Finally, formal preparation of teachers, administrators, and community representatives is essential in successful programs. In many areas, the formalization of school/community relations is novel, and necessary skills and strategies are unfamiliar to the key participants. The persons who provide training will vary across situations, but will likely involve some combination of school and community personnel. It is hoped that attention to establishing school/community partnerships will become an integral component in preservice professional preparation programs across colleges of education and business. Until this time, however, comprehensive and integrated in-service training will be necessary.

BEST PRACTICES

Identifying Resources and Establishing Partnerships: A Problem-Solving Approach

School/community partnerships can be operationalized and implemented in a number of ways. Just as no two schools and no two communities are alike, no two partnerships are identical in structure, purpose, or procedure. Although several examples are now available to schools and communities interested in forging a productive relationship, the means by which the partnership actually takes shape must be determined by the needs of the participants. Thus, a structured, ecological problem-solving approach (Kratochwill & Bergan, 1990) may be beneficial in developing, implementing, and evaluating school/community programs.

Problem Identification and Goal Formulation

When establishing a partnership of any kind, participants must clarify the scope, purpose, and objectives of the relationship. This entails specifying clearly why the partnership is necessary (i.e., the "problem" it is meant to prevent or resolve), and what the partnership is intended to accomplish (i.e., the goals). Although school/community programs may be desirable in their own right, they will not sustain themselves if they do not serve a specific and concrete purpose. Therefore, members of the partnership must establish clear lines of communication and jointly determine the primary areas of need, estimated prevalence rates, and appropriate goals for the school/community program.

One can identify problems at an individual classroom, school, or district level. As with all prevention programs, the broader the level at which a need can be defined, the more far-reaching are the effects. A comprehensive needs assessment should take place during the problem identification stage. For example, as a school psychologist working in an inner-city, overcrowded high school, you may recognize that student achievement in your school is significantly lower than in other district high schools. By investigating characteristics of the school (e.g., technological and material resources, instructional opportunities in technical skills, volunteerism, neighborhood businesses) and those common to several students in the school (e.g., computer literacy, after-school activities, later life aspirations), you will be in a position to specify salient school and student needs and develop objectives for school/community programs. The likely goals of such programs in this school would be to raise student achievement, equip students with meaningful life skills, and prevent current and future problems (e.g., dropping out, delinquency, academic failure).

Ecological Analysis

To truly understand problems in the school or community, one must carefully analyze environmental strengths and limitations, examining variables within the school and community that perpetuate existing problems. For example, the existence of a significant gang culture in the high school described above may foster lack of interest in academic achievement and school programs by students and community persons alike. Likewise, the school historically may have been isolated from the community due to lack of confidence in the school's ability to teach basic skills and prepare its students to compete in the work force. By generating hypotheses about the nature and function of the problem (in other words, *why* it occurs), one can explore appropriate and meaningful partnerships.

An important aspect of ecological analyses is identifying resources that can help solve the problem. It is essential that human, material, technological, financial, and informational resources be explored before committing to any one type of partnership. Likewise, a multisource, multisetting consideration of resources should be invoked, including those available within student, home, school, and community agencies. A matrix such as the one depicted in Figure 2 can be employed when considering the various resources that may be available in developing school/community partnerships. Note that a discussion of home/school partnerships and use of home resources is beyond the scope of this chapter; readers should consult Christenson (this volume) for extensive coverage of this important topic. Suffice it to say that consideration of the home environment and parental involvement in the development of school/community linkages should not be overlooked.

Plan Development and Implementation

The actual development of a school/community program should occur via brainstorming with all key persons from schools and communities. When brainstorming, participants should think creatively, withhold judgment, and pool ideas and options to create even more alternatives. Possible programs may include aspects of or entire models available in the literature, such as those described later in this chapter. On the other hand, novel and unique alternatives may be generated when individuals from various constituencies pool their ideas and expertise. Indeed, the ability to share responsibility and offer varied options is a cornerstone of school/community partnerships. In the example above, increased involvement of volunteers in the school may be desirable to students with academic difficulties and teachers, and to change the perceptions of community persons. Likewise, an after-school sports program, staffed by coaches at the local community college and supported with equipment donated by a neighborhood sporting goods store, may decrease gang activity and keep students and local agencies interested and active in the school setting. Finally, community-based training in such skills as computer programming, gourmet cooking, mechanics, or child care can be instrumental in extending the formal educational experiences of students into meaningful, lifelong vocations.

Implementing a school/community program requires a great deal of organization and leadership. It is best to identify a key person in the school and a key person in the community to ensure that the details of the program are clear to all participants, the strategies are followed with integrity, and communication remains open. Specific written guidelines in the form of a management plan maximize smooth operation of the program. As mentioned earlier, the components of the management plan should specify what, why, where, how, and by whom the tactics will be instituted.

Plan Evaluation

Best practices of any school-based service delivery model dictate that the effects of the model be evaluated. School/community partnerships are no exception. When promoting and implementing these types of educational programs, one should evaluate benefits, limitations, and intended and unintended side effects; reassess prevalence rates; and examine

FIGURE 2. Resource matrix.

	Physical	Technological	Information	Financial	Human
Student					
Home					
School					
Community					

attainment of the concrete goals of the partnership. Both formative (process) and summative (outcome) evaluation practices can be instrumental in the overall assessment of the effects of school/community partnerships. Participants should also assess consumer satisfaction with the program (i.e., students, parents, schools, businesses, other community participants), and finally explore long-term benefits and liabilities.

MODELS OF SCHOOL/COMMUNITY PARTNERSHIPS

Although several models of school/community partnerships are available in the literature, research on the effectiveness of the various approaches is extremely limited. In general, programs can be based within the school (with community agencies entering school buildings and providing training or support), or within the community (with instruction and training occurring outside the school building). The objective of the various programs differ, as do the required resources and the expected outcomes. To reiterate a point made earlier, the needs of the school, students, community, and other educational patrons must be considered in determining the most appropriate type of partnership.

School-based Approaches

Although attention to school/community partnerships has increased drastically over the last decade, most programs continue to be school-based. Examples of models involving community persons or resources in the school building itself include volunteerism and Adopt-a-School programs.

School volunteers. The most common form of community involvement in education takes the form of school volunteers (Gonder, 1981). Trained volunteers can provide several important functions in the school building, including conducting vision, hearing, and developmental screenings; providing individualized tutoring for students with special academic needs; monitoring behavioral programs; and helping to develop curricular materials. When directly involved in academic and instructional activities, volunteers lower the pupil–adult ratio in classrooms.

An important variable in the effectiveness of volunteer programs is recruitment. In a review of several volunteer programs, Gonder (1981) emphasized that "successful volunteer programs place a high priority on recruitment. The sensitive school district tries to recruit volunteers from all races and ethnic groups to serve the needs of their students. Another rich source is the retired community. Students and employed persons are also willing to volunteer" (p. 300). Indeed, the days are gone when volunteers involved only white, middle-class, nonworking mothers serving as "room mothers" and providing baked goods for the bake sale.

Adopt-a-School programs. Adopt-a-School programs match a particular school with a particular business according to teacher-identified student needs. While most Adopt-a-School programs involve primarily school-based activities, educational field trips to businesses allow for important community experiences. Such programs are especially successful in large cities with a well-organized business community (Tangri & Moles, 1987).

An important consideration of Adopt-a-School programs is that through such partnerships, both schools and community agencies benefit. For example, students have opportunities to hear guest speakers, tour facilities, and participate in innovative programs. Likewise, businesses enjoy a positive public image while their employees obtain community service experience. Such programs also enable employees to demonstrate leadership skills, creativity, and other desirable traits that may not be readily observable in their day-to-day job responsibilities (Gonder, 1981). Although one barrier to Adopt-a-School programs is the lack of teacher involvement, teachers also can benefit greatly by establishing professional contacts in the community.

Community-based Approaches

An exciting alternative to school-based programs are those that provide training and instruction in the community itself. In essence, these programs extend the walls of the school building to incorporate businesses, community agencies, and other work settings. These types of instructional experiences promote generalization of academic learning to the actual setting in which it is used. Examples of community-based approaches include vocational and career education programs, experience-based career education, and community as classroom programs.

Vocational and career programs. The defining characteristic of vocational and career educational programs is that students are taken off campus for part of their schooling. The programs vary tremendously, from those that provide occasional field trips to those that provide a steady, paid job to students. Common to all programs is that they ensure adult supervision for the activity, integrate the activity with the students' academic requirements, and elicit participation of members of the larger community (Tangri & Moles, 1987). Objectives of vocational programs include enhancing students' performance in traditional academic subjects; increasing students' knowledge about vocations and methods of coping in the real world; and improving the satisfaction of educators, parents, students, and the general community.

In general, students in vocational programs are involved for two years. They work at their own pace to master objectives set by the business community in jobs such as computer technology and cosmetology. In their second year, they seek on-the-job training that may lead to paid jobs (Gonder, 1981).

The vast majority of vocational and career programs are implemented at the secondary school level. Little or no attention to such programs at the elementary level appears in the literature. To receive federal funding, programs are required to enroll at least 15% educationally disadvantaged and 10% handicapped students. Sex discrimination in federally funded programs is also prohibited.

Experience-based Career Education. Experience-based Career Education (EBCE) was designed to bridge the gap between high school coursework and experience, and between the classroom and the community (Bucknam & Brand, 1983). In EBCE programs, students move off campus for firsthand experiences in such community settings as offices, stores, factories, hospitals, and government agencies. Off-campus sites become the primary setting in which curriculum is delivered, via planned experiences as bases for learning academic subjects. Such a program differs from others in which community visits are brief. Students in EBCE programs earn academic credit rather than pay; thus all learning experiences in the community lead directly to a regular high school diploma.

For EBCE programs to be successful, policy directives are provided by an advisory board comprised of individuals from business and labor, parents, students, and other community interests. However, the programs require students to take a greater role in shaping their own educational plans. They are also designed to integrate a variety of student populations.

Whereas little or no empirical studies have addressed most school/community programs discussed thus far, EBCE has received some attention in the research literature. In a meta-analysis of 80 evaluations of EBCE, Bucknam and Brand (1983) found that in the majority of studies (a) EBCE students made large gains not only in career skills and life attitudes, but also in academic skills; (b) EBCE students gained more than students who received the typical high school curriculum; (c) greater gains were noted in programs with high fidelity (i.e., those that followed standard procedures) than those with low fidelity, although students in these latter programs also made gains; and (d) students at all socioeconomic levels from all types of residential areas profited from EBCE experiences.

Community as classroom. Programs that fall under the class of "community as classroom" deliver important academic curricula outside of the school building, but the nature of the work is not vocational, career, or work education. However, they do use donated community resources (such as church basements) to hold regular classes, and both the school and community benefit. Some instruction may be delivered in settings specific to the subject matter, such as nature centers, arboretums, or historical parks. Some students are also able to take courses for col-

TABLE 1
Recommendations for Breaking Down Interagency Barriers

Create interprofessional programs for training professionals.

Create solutions that bring diverse groups together for a period of time.

Find legitimate ways to deal with confidentiality problems.

Examine existing categorical program structures and make changes if necessary.

Link information systems in a systematic fashion.

lege credit from a community college (Tangri & Moles, 1987).

A potential difficulty with community-as-classroom programs is the logistical problems of securing a location and gaining entrance. Likewise, some high school students are not responsible enough to enjoy their autonomy and still complete the academic requirements of off-campus programs. Nevertheless, most of these programs have yielded positive results. For example, many students are able to complete their high school graduation requirements in less than the traditional four years in community-as-classroom programs (Gonder, 1981).

INTERAGENCY COLLABORATION: THE SCHOOL'S ROLE IN COORDINATED SERVICES DELIVERY

A different, albeit critically important form of school/community partnership consists of collaborative relationships between multiple agencies, including the school, all bearing some level of responsibility for meeting the needs of children. Several factors have arisen in recent years contributing to the need for schools to work more closely with health, social services, and other youth-related institutions. Current societal conditions include homelessness, AIDS, family dissolution, adolescent pregnancy, alcohol and drug abuse, and suicide. However, at least 25% of children are not covered by any form of health care. Two-thirds of the children and adolescents who need mental health services receive either no services or those inappropriate to meet their needs (Knitzer, 1982; Saxe, Dougherty, Cross, & Silverman, 1987). Cutbacks in social services have produced counselor caseloads of 250–500 students. Medical attention in schools, once available through school nursing services, has also been cut, and many nurses now visit a different school each day (Achievement Council, 1988).

Many agencies, institutions, and organizations exist in communities, most of which should be available to children and families. Existing educational legislation (e.g., Public Law 94–142; Public Law 99–457) mandates that students with special needs *must* be provided with those services necessary to meet their unique educational and related needs. According to Apter (1992), "nothing in the law prohibits the school from utilizing other nonschool community services and funding where they are available" (p. 490). The reality, however, is that coordination of the multitude of services some children require is haphazard, incomplete, or nonexistent. Services that are offered often do not meet the complex needs of children and families (Knitzer, 1982, 1993).

Several factors evident in schools, families, agencies, and communities limit linkages. These include funding policies at the local, state, and national levels; lack of communication networks between families and agencies; little training of school personnel in establishing collaborative relationships; issues of "turfism"; unstructured referral mechanisms; and allegiances to employing agencies, rather than to families and children (Apter, 1992; Bucci & Reitzammer, 1992; Hazel, Barber, Roberts, Behr, Helmstetter & Guess, 1988). Recommendations for breaking down barriers are presented in Table 1.

Regardless of the reasons why these barriers exist, the fact remains that parents have extreme difficulties identifying and accessing services on their own (Featherstone, 1980). Schools have been suggested as appropriate settings to function as a "hub" of service delivery (Knitzer, 1993). Given that children with special needs often are identified initially by school personnel, and that schools are one societal agency available to everyone (Apter, 1992; Kirst & McLaughlin, 1989; Shedlinn, Klopf, & Zaret, 1989), it may be most appropriate for the locus of systems coordination to occur in the school setting. According to Ascher (1990), "because all children have to attend schools . . . [and] because schools are supposed to be concerned with their students' overall development, it is logical for them to coordinate students' contact with human service agencies." In keeping with the correlates of collaborative partnerships, "not only will access to health, employment, and social services be improved if they are located in schools, but . . . school policies can be influenced positively by professionals from these disciplines" (p. 1).

Schools, and particularly school psychologists, *can* play a primary role in coordinating services for students and families. However, few clearly defined, operationally specific models exist to provide struc-

TABLE 2
Characteristics of Successful Interagency Collaborations

Successful interagency collaborations:

1. Are both top-down and bottom-up;
2. Involve parents and children from the start;
3. Make clear that the school is a partner, but is not in charge;
4. Link services to additional school restructuring efforts;
5. Offer a wide array of services or provide easy entry to services;
6. Move beyond crisis management and early intervention to prevention and development;
7. Cross professional and bureaucratic boundaries to offer coherent services, often at nontraditional hours in nontraditional settings;
8. Provide staff with the time, training, and skills necessary to build relationships of trust and respect;
9. Hire one staff member from the local community to act as facilitator;
10. Deal with the child as part of the family, and the family as part of the neighborhood or community; and
11. Utilize a new system of accountability.

Adapted from Ascher (1990) and Kirst (1991).

ture and guidance in the development and implementation of this complex service delivery model. As emphasized earlier, a solutions-oriented problem-solving approach may be most appropriate for coordinated services. In this type of model, the specific needs of a target child and family determine the manner in which resources are identified and accessed. Characteristics of successful collaborative partnerships, which relate also to the types of school/community relationships discussed in the first part of this chapter appear in Table 2.

A number of formats can be used to implement a coordinated services approach. As suggested, it may be most appropriate for services to be "school-linked" (Kirst, 1991). This does not mean that the school dominates the organizations of delivery of services, or that the school is financially responsible for the coordinated care. Rather, it means that the school is the location in which services come together. The program defined as an "interagency system linking schools and local and private human service agencies with the support of business, higher education and other community resources to meet the interrelated educational, social and psychological needs of children" (Kirst, 1991, pp. 6–7). In the spirit of collaboration, such programs benefit all who are involved by empowering the various constituencies (i.e., parents, schools, agencies) to become more effective and efficient service providers and consumers.

Various types of school-linked models are possible. For example, a "case management" model can be used, wherein an individual within the school (e.g., teacher, social worker, psychologist, counselor) is assigned to help a student receive needed services. A "programmatic integration" approach requires that a school and agency link to deliver a particular service or range of services. A third model is that of "co-location," where necessary service providers (e.g., nurses) are brought into the school, often at the expense of a foundation or agency. "Community coordinating councils" are councils that integrate mental health, social services, education, and employment. These councils typically are appointed at the city level (McLaughlin, 1989).

The Early Childhood Direction Model (Apter, 1992) is a New York state network of information, support, and referral centers that offer technical assistance to families and children from birth to age five. The operative mechanisms of Early Childhood Direction Centers (ECDCs) may serve as a model for establishing smaller-scale coordination programs in schools. According to Apter (1992), "the concept of 'direction service' has to do with a family-centered, single coordinating entity designed to assist families in negotiating the maze of services and developing a coordinated plan to meet their needs and those of their disabled child" (p. 490). Centers involved in the network are each responsible for several functions, including conducting active-finds, maintaining current resource information, assisting parents with transition between various educational programs (from preschool to elementary school and beyond), and providing information, referral, support, and follow-up to parents and professionals.

In the spirit of a problem solving orientation, ECDCs are charged with assisting families to identify their own specific issues and problems, locating appropriate support agencies, making timely referrals, helping parents access those services, and following up over brief and lengthier time intervals. Although such programs can be costly, there is some evidence to support their utility (Musumeci & Koen, 1982). Readers interested in obtaining more information about ECDCs are referred to Apter (1992) and Zeller (1980).

SUMMARY: SCHOOL PSYCHOLOGISTS AND SCHOOL/COMMUNITY PARTNERSHIPS

In the current zeitgeist of educational restructuring and reform, the role of the school psychologist can change drastically. One function that school psychologists should strive to adopt is that of liaison between homes, schools, and communities. A number of strategies by which schools can be linked productively with communities have been explored in this chapter. Clearly, the role of the school psychologist in these programs will vary. School psychologists are perhaps the most logical and best-trained individuals in educational settings to establish and implement school/community programs. However, the degree to which school psychologists take on leadership functions must be in line with individual levels of interest, time, and training. A particularly important consideration is the amount of administrative and staff support available in psychologists' work settings. Specifically, the development of such programs will take a great deal of time and effort, and hence should not be considered an "add on" responsibility. Rather, the manner in which psychological services are defined must change. Case loads, assessment tasks, and direct service responsibilities should be shifted to allow the school psychologist to function adequately and effectively as program developer. Likewise, given the systemic structure of schools, families, and communities, the roles and relationships of all individuals within the educational community must be redefined. Indeed, this is no easy task. Perhaps the most pragmatic approach is to "think big, start small, go slow" (Welch & Sheridan, in press).

This chapter provides an extensive overview of models and programs for school/community linkages. The focus of the

BEST COPY AVAILABLE

chapter is assisting families to identify and access appropriate, integrated, and comprehensive services. The chapter provides a detailed description of a "direction model," which can serve as a framework for school psychologists. It also includes case examples with helpful guides and other strategies for linking families to resources.

Knitzer, J. (1993). Children's mental health policy: Challenging the future. *Journal of Emotional and Behavioral Disorders, 1,* 8–16.

In this timely article, Knitzer provides a historical overview of issues in children's mental health, outlines the need for a paradigm shift in the delivery of services, and describes various considerations in the development of integrated service models. In particular, the author examines issues surrounding research, training, and legislation regarding children and families. This is a very comprehensive and important essay for school psychologists interested in restructuring children's mental health services at the policy and practitioner levels.

National Association of State Boards of Education. (1992). *Partners in educational improvement: Schools, parents, and the community.* Alexandria, VA: Author.

This concise overview of parent and community involvement in education describes various benefits, models, and principles of successful partnerships in a pragmatic, succinct manner. Further, the report discusses important implications for policy and leadership and provides resources for parent and community involvement and contacts for several states. The report is available from the National Association of State Boards of Education, 1012 Cameron Street, Alexandria, VA 22314.

Best Practices in Preschool Screening

Ball State University

OVERVIEW

The term "screening" can have a variety of meanings. In this chapter, screening refers to brief, global, relatively low-cost procedures used to obtain preliminary information about a wide range of behaviors for large groups of children. In turn, this restricted sample of information is used to roughly estimate a child's skills and abilities, characteristics of the child's environment, and ways these may interact. The focus will be on screening during the period when children customarily make the transition to traditional school experiences. Many of the procedures discussed are geared to "kindergarten roundup" where children are screened just prior to school entrance or to screening conducted early in the kindergarten year. Such screening may have more than one purpose including:

1. Early identification of potential learning problems.
2. Referral of children for further evaluation/assessment.
3. Obtaining essential health and background information.
4. As an aid to development of programming and/or experiences based on individual children's needs.
5. Engagement of parents to ensure appropriate development of their children through recognition of individual strengths and weaknesses.

Including purposes 4 and 5 in the above list may cause some consternation for clinicians concerned lest screening replace more thorough assessment. However, there is no cause for alarm. The authors of this chapter certainly do not advocate that screening be used to replace complete evaluation where such assessment is warranted. Screening procedures are typically less reliable and valid than those used for individual assessment and should not be used to make diagnoses nor to label children. However, it should be recognized that for a great majority of children such individual assessment is neither feasible nor necessary. Information from screening can be valuable to help increase the chances of early school success for all children by providing tools for parents and teachers to tailor experiences and curricula to individual needs.

The value of early intervention has been well established (see Harrison, 1992, for a good review). Indeed, Dunst (1986) argued that the time has come to stop asking if intervention works and to start exploring how to better identify problems in order to improve therapeutic and educational services. Only through early identification, effective family involvement, and intervention can real behavior change be expected to occur.

Obvious problems which may interfere with learning are usually hard to ignore and may have been identified long before a child reaches kindergarten entry. This should become increasingly true as the impact of Public Law 99-457 is felt. Once "child-find" procedures for children from birth to age five are universally instituted, screening just prior to or soon after school entrance will no longer play as important a role as it currently does in initial identification of children with disabilities and/or who are at risk for school failure. However, it is expected that such screening will remain important (a) to identify children missed earlier, (b) to determine "hidden" problems which may not be easily identified, (c) to serve as a quick check of previously instituted interventions, and (d) to help provide information for developing programming and individualizing instruction for all children. The latter purpose becomes more important as efforts towards inclusion and restructuring take form during the next few years.

One often overlooked advantage of early screening programs is the opportunity to engage parents in the education of their children and in a positive relationship with school systems. By soliciting the help of parents during this early introduction, school personnel have a golden opportunity to emphasize how essential it is for parents to be involved in the education of their youngsters. Parents can help their children to be more effective in school, both through focusing on strengths and weaknesses identified during screening, and through increased involvement and communication with the school. This process also provides a vehicle for the beginnings of conversation dealing with acceptance of problems and subsequent positive attitudes toward amelioration of these. Indeed, screening may be the first time that parents have been faced with realities involved with youngsters whose development lags behind others of their age group.

The use of screening to determine inclusion or exclusion in kindergarten seems to have become prevalent. Yet many, including these authors, do not recommend such practice because of their belief that excluding children from kindergarten based on screening is not sound. For example, kindergarten curricula are becoming increasingly academic in their orientation. This trend is counter to that recommended by early childhood educators and to the position taken by the National Association of School Psychologists (NASP). All too often accompanying such practices may be a failure to recognize the individual nature of learners which in turn mediates against making appropriate adaptations in curriculum and instruction to accommodate individual differences. The practice of excluding youngsters deemed "unready" is also an extension of the philosophy that difficulties are primarily child centered rather than the result of the interaction between characteristics of the child and his or her environment.

The purposes of this chapter are to (a) discuss advantages and disadvantages of early screening, (b) present an ecological problem-solving model of screening, (c) present guidance in using this model for developing and implementing screening, (d) present suggestions for instruments and procedures to be included, and (e) highlight ways in which to engage parents in screening and the subsequent education of their children. An ecological-problem solving model which takes into consideration not only child variables but also the environment is presented in the Basic Considerations section which follows.

BASIC CONSIDERATIONS

Many school districts are able to use screening results to make informed decisions to help children become better learners as well as engaging parents and teachers in the process. Unfortunately, in spite of its many benefits, there are some pitfalls connected with early screening. First, care must be taken to ensure that the results of screening are used appropriately. Indeed, screening measures and procedures should not be used for diagnosis or for attaching labels to children (see NASP position paper on Rights Without Labels).

Second, preschoolers differ both quantitatively and qualitatively from school-age children. Care should be taken to select procedures developmentally appropriate for preschoolers (Peterson, 1987). Additionally, even under the best of circumstances, many preschool instruments have lower reliability than those used for school-age youngsters.

Third, it is normal for behaviors of children in this age group to change dramatically from one time period to the next and from situation to situation. These children are not stable responders for a number of reasons. For example, they may have underdeveloped social skills, be wary of unfamiliar adults and situations, be anxious at being separated from parents, be distractable, have short attention spans and lack concentration skills, have limited verbal skills, and lack knowledge about the purpose and the importance of testing. For the most part, these children have as yet not learned to be "students." Therefore, care must be exercised in selecting procedures and interpreting results.

Prevailing procedures used for screening too often focus on a strictly child-oriented model. Unfortunately, even the best child-centered measures leave a great deal to be desired when their ability to predict outcomes is considered. For example, setting cut-off scores for determining those at risk versus those not at risk has been found to be, at best, questionable. Even with the best predictors, only about 45% to 65% of students predicted to have difficulties based on preschool screening really did have problems in learning by second grade. Generally, results of follow-up studies indicate that while those students who generally do well on screening measures can be predicted to succeed, those who do poorly may or may not be successful. Cut-off scores can be adjusted to eliminate some of these "false positives." However, it is not clear how many youngsters with real difficulties will be overlooked in the process.

Because of the inability to determine which children will succeed or not through examining child behaviors, school psychologists increasingly have sought answers through consideration of home and school variables. Indeed, a child's success or failure in school can be conceptualized as a function of the interaction between individual characteristics such as developmental status, temperament and motivation, and specific environmental factors found in the home and classroom. Such an interactional or ecological model results in goals for screening incorporating the view that school success is due not only to the skills and behaviors of the child but the congruence between these and the characteristics of the classroom situation. This has resulted in an accompanying shift of focus from problem persons to problem environments and allows for models which take into account not only the child and his or her environment but the interaction of the two.

If the primary goal of a screening program is to enhance early school success, such a program must incorporate important knowledge about characteristics of the child's environment. A major advantage of using an ecological model is the implication that problems can be potentially resolved through a range of alternative strategies such as: (a) modifying the problem behavior, (b) changing the expectations of parents and teachers, and/or (c) altering the situation (Barnett & Paget, 1988). Another important ramification of studying whole systems is that if the child does not "own" the problem, then a significant number of problems may never need to be assessed because they can be prevented through appropriate modification of environments (Adelman, 1982).

In spite of the emphasis placed on earlier identification, it is possible that during screening children may be identified who have significant delays. In this case referral for further assessment is mandatory. In addition, this may provide an opportunity for school personnel to help parents begin to deal with the changes necessary to accommodate youngsters with difficulties. It is very possible that these parents have been denying that a problem exists.

The following outline represents one problem-solving approach based on an ecological model. The Best Practices section following this list examines each step in detail.

1. Determine the purposes of screening and decide how the results will be used.

2. Select domains to be sampled.

3. Select assessments and procedures that provide for collection of useful information from and about important individuals in each environment.

4. Choose personnel and plan logistics.

5. Analyze data within and across contexts comparing data from and about various sources.

6. Provide feedback for parents and recommend experiences designed to enhance the child's chances for success.

7. Evaluate and revise procedures where changes might result in more efficiency, greater communication, and/or smoother integration of systems.

BEST PRACTICES

Step 1. Determine the Purposes of Screening, and Decide How the Results Will Be Used

As mentioned earlier, screening may be conducted for a number of purposes. If the aim of screening is merely to differentiate those students who need further evaluation from those who do not, a low-cost, quickly administered multipurpose screen may be adequate. However, the best screening programs include information from a variety of domains, across a variety of environmental settings, and from a variety of sources (Bailey & Wolery, 1989; Lichtenstein & Ireton, 1991). At a minimum, arrangements should be made to see the child and to obtain information from the parent(s), preschool teacher, and/or other professionals involved with the child, and about home and school/preschool environments. While integration of these data may be time consuming, actual collection from a variety of sources may be accomplished quite expediently.

Once the purposes for screening have been determined, the task is to choose specific areas to be screened. Some domains often sampled are described in Step 2.

Step 2. Select Domains to Be Sampled.

Whatever its intended purpose, screening should include information about behaviors from a number of different domains. Decisions about which domains should be emphasized and which information should be collected depends on the purposes of the screening as well as other factors. However, cognitive, language, and social/adaptive behavior information has been shown to be most predictive of school success. Speech, fine and gross motor, and perceptual abilities have been found to be related to a lesser degree and are usually not predictive unless problems are severe. The following nine domains represent the most common areas screened.

Health. Screening for visual and auditory acuity may accompany or precede screening. Such information is essential in helping evaluators rule out physiological bases for behaviors. Parental input is essential in providing information about perinatal history, developmental milestones, immunizations, health problems, and the like.

Cognitive/basic concepts. This area includes a wide range of mental abilities including association, reasoning, memory, and understanding of basic concepts. Basic concepts are rudimentary, functional vocabulary terms that refer to general ideas or characteristics which are applicable to several objects or events and help us mentally organize our world. Children must learn many basic concepts before they can be successful in school. Some examples are relationships of objects one to another (e.g., over, under, beside, next to, and behind), size, texture, quantity, time, shapes, colors, letters, numbers, and social relationships. It is better to focus on basic concepts rather than the more general aspect of cognitive or intellectual ability because of the potential for abuse of such terms and information. Too often parents and teachers may make unwarranted assumptions about a child based on presumed ability information. By the time they are four or five, youngsters are learning about time and weather, likenesses and differences, and categorization. They can answer "why" and "how" questions and are becoming aware of community people and places.

Speech and language. The development of speech and language is a remarkable accomplishment. Each child must learn speech sounds, words and their meanings, to combine words to make understandable sentences, and to use sentences to communicate with others. Ordinarily, by the time a child is four or five years old, she has mastered all of the sounds of her language, has a vocabulary of approximately 2,000 words, can follow conversations, and use polite forms such as please and thank you appropriately.

Gross and fine motor. Motor skills include large motor movements, coordination, balance and equilibrium, eye-hand coordination, manipulation of objects, use of paint brushes and scissors, grasping patterns, and imitation of body movements by visual cues. By the time children are ready to enter kindergarten, they can move quickly and purposefully in many ways. They are strong and confident and quickly follow directions. Many are able to ride bicycles with the use of training wheels. Most can trace their own names and print several letters. They draw simple persons with three or four body parts, copy simple shapes, color within the lines, and put together simple puzzles.

Behavior/temperament/socioemotional. Some useful components in screening of this domain include the child's activity level, social interactions, relations with same-age peers, typical affect, ability to follow directions and focus attention, play style, anger control, and sleep and eating patterns. A typical five-year-old is fairly independent, respects authority, and is interested in group activities. She can share with others and wants to go to school.

Self-help. In order to be successful in kindergarten, children must be self-sufficient in caring for their everyday needs. By the time a child is ready to enter school, he often can tie his shoelaces, can be given two or three tasks to do, and will carry them out in order. He dresses himself and is semi-independent at clean-up and grooming tasks.

Visual perception/motor integration. Visual perception refers to the process of interpreting what is seen. This goes beyond the acuity information obtained through health screening to include such areas as recognition of similarities and differences (discrimination); seeing a figure as distinct from its background (figure ground); ability to orient oneself in space (spatial relations); recognition of images when they vary in context such as size, shape, color, or placement (constancy); and integration of visual and motor skills. Items measuring visual motor and perception skills may overlap with those used to measure motor functioning, because fine motor control and eye-hand coordination are included. Also important are the ability to remember visual sequences, draw two-dimensional forms, reproduce three-dimensional visual structures, visually discriminate among common objects, and demonstrate visual-spatial analysis and synthesis. Children entering kindergarten generally must be able to sustain visual attention, discriminate, remember, and use visual closure skills quickly enough to produce comprehension.

Auditory perception. Auditory perception refers to the ability to understand speech sounds given that one can hear comfortably. Auditory perception includes the ability to listen and to repeat information given, to receive and process auditory stimuli, to respond to questions heard, and to discriminate among speech sounds. Most five-year-olds are able to discriminate most of the sounds and patterns common in their native language. Problems with auditory perception are often manifested in delayed language acquisition, poor oral expression, difficulties in remembering sequences, and the like.

Home environment. This domain includes aspects of the home environment and parent–child interactions. For example, questions might be asked about types of play materials; kinds of books in the home; the frequency with which parents read, talk, and play with the child; and the amount of responsibility given to the child. Other areas might include the importance placed on work, achievement, and success; the extent to which education and school-related activities are encouraged and supported; interest placed on intellectual, ethical, and cultural activities; and the extent to which exchanges of ideas and decisions are encouraged and valued. Sample questions to guide information gathering include:

- What kinds of communication exist among family members?
- Does the family function as a support system?
- What is the organization of roles and responsibilities?
- What is the nature of the interaction of child and parents?

In order to tap at these domains, a number of strategies may be chosen. Information about procedures that can be used to gather this information is given in the following section.

Step 3. Select Assessments and Procedures that Provide for Collecting Useful Information from and about Important Individuals in Each Environment

The model for selecting screening procedures given here follows suggestions made by Bagnato and

Neisworth (1991) for their protypical assessment battery for preschoolers. They suggest gathering norm-based, curriculum-based, judgment-based, and eco-based information. This framework is used in the following section; for more information about specific instruments and/or procedures, the reader is directed to Bagnato and Neisworth, 1991, Paget and Barnett, 1990, and Bracken, 1991.

Norm-based. Norm-based assessments compare a child's performance with the performance of a given group thought to be typical or similar to that child. Although national norms are useful for comparing children with their peers throughout the U.S., local norms also compare them with their more immediate peers. This can be an important consideration when the characteristics of standardization samples do not closely match those of your group. Even with difficulties associated with norm-based instruments, they remain one of the most reliable and efficient ways to collect information. They provide for quick collection of broad-based information about a number of important domains. The number of instruments designed specifically for screening of preschoolers has increased rapidly over the past few years. Not only are there more choices available, but the instruments themselves have been improved greatly. Although norm-referenced instruments should not be used in isolation from other factors in the child's environment, it can be useful to include at least one in the screening battery. In fact, because a number of the newer instruments provide for gathering information in judgment- and eco-based contexts, it might be wise to reexamine norm-based screening procedures in light of the improvements made in the past few years. To aid in such a reevaluation, the following list of selection criteria was culled from suggestions by a number of authors (e.g., Bailey & Wolery, 1989; Lichtenstein & Ireton, 1984) as well as the authors' personal experiences.

1. Screening should include information about behaviors across a wide variety of environmental settings and from a variety of sources.

2. A profile of outcomes is preferable to a single score.

3. Evidence for adequate standardization and assessment of psychometric properties such as reliability and validity is provided.

4. The screening must be acceptable to its primary users. Those using the instrument must feel confident about its use both from a practical point of view and from the confidence they feel about its usefulness.

5. The focus is on developmental tasks rather than those that tap at learned information that is influenced a great deal from experiential opportunities not available to all children.

6. Procedures include provision to systematically gather information from parents.

Curriculum-based. Curriculum-based procedures are referenced to skills and competencies expected for kindergarten success. Criterion-referenced tests are developed from curriculum content, and skill attainment is compared to the child's previous performance rather than to that of a group. Criterion-referenced tests extend from a task-analytic perspective and emphasize individualized instruction. Criterion-based instruments are not without their problems. For example, too much emphasis on the acquisition of skills with which the child has had little experience may lead to the erroneous conclusion that the child is not ready for the demands of school. One must always seek to ascertain whether a child has been unable to attain certain skills because of some difficulty in learning or because he or she lacked appropriate experiences and/or instruction.

Some representative criterion-referenced tests include the Brigance Inventory of Early Development (Brigance, 1979), the Brigance K and 1 Screen (Brigance, 1987), Beginning Milestones (1986), and the Portage Guide to Early Education (Bluma, Shearer, Frohman, & Hilliard, 1976).

Judgment-based. Judgment-based procedures include parent and professional perceptions of child status and progress. Judgment-based measures are useful for many reasons. Examples of formal measures used to provide information include the Child Behavior Checklist (Achenbach, 1991), Personality Inventory for Children (Wirt, Lachar, Klinedinst, & Seat, 1984), Social Skills Rating Inventory (Gresham, F. M., & Elliott, S. N., 1990), and Temperament Assessment Battery (Martin, 1988). As mentioned earlier, many of the multidomain screening instruments also include a brief measure of parent and/or clinician judgment of behavior.

Perhaps the most essential ingredient of any successful screening program is the parent(s) or other caregiver. Parental involvement is critical for a program's success from a number of different perspectives. Parents see their children on a day-to-day basis and know behavioral patterns over the years. Thus parents' descriptions are of behaviors as they occur naturally and are therefore more reflective of what youngsters can actually do. Information and observations garnered during the actual screening process may be influenced by the strange situation phenomenon whereby youngsters are forced into environments unlike those they know and understand. Table 1 provides an overview of research validating the importance of parental input in preschool screening.

Input from others is also important. For example, preschool teachers and other caregivers can give important information to help explain other screening results. Observations and ratings by those administering the screening also provide important informa-

TABLE 1
What Research Indicates About Using Parent Input in Preschool Screening

Research Study	Sample Description	Instrumentation	Research Findings
Bagnato (1984)	54 infants and preschool children with multiple disabilities and their mothers	Multiple clinical judgment and performance measures	1. Mothers have extreme sensitivity to subtle changes in their children's behavior 2. Including mothers on the diagnostic intervention reduced parental anxiety. 3. Team approach improved mother's motivation to be involved in intervention
Harrington (1984)	3008 black and white children from urban areas in Indiana and Washington state	Mother's report from Developmental Profile	A correlation of .84 between the Stanford-Binet mental age and the Developmental Profile academic age
Colligan (review of 7 students, 1982)	1,413 children from seven studies	Subjective and objective performance criteria	The use of parent questionnaires in preschool screening as a means of obtaining useful, economical information about the potential difficulty of prekindergarten children in the early school years was supported in each of the seven studies
Lichtenstein (1982)	391 preschool children aged 49 to 64 months and their parents	1. Minnesota Preschool Screening Instrument. 2. 28-item developmental inventory to parents 3. Teacher ratings of kindergarten performance one year after screening	1. Positive relationship between parent reports of developmental functioning and early school performance 2. Although validity rates for parent report measures were promising, this study did not suport the sole use of parental information in preschool screening as a substitute for direct testing.
Eisert, Spector, Shankaran, Falgenbaaum, and Szego (1980)	Children aged 2 to 5 years	Minnesota Child Development Inventory (MCDI) completed by parents	1. High correlation was found between the parents' perceptions on the MCDI and results of objective cognitive tests (McCarthy Scales of Children's Abilities and Stanford-Binet)

tion about a child's approach to a particular task, general activity level, and the like.

Eco-based. Eco-based procedures characterize the social and physical qualities of the child's developmental context, especially the family. Currently available eco-based measures that examine either the context or the interaction of the child in the environment include Home Observation for Measurement of the Environment (Caldwell & Bradley, 1978), Early Childhood Environment Rating Scale (Harms & Clifford, 1980), and the Parenting Stress Index (Abidin, 1986). Although these instruments are not designated primarily as screening instruments, many are relatively easy and quick to administer.

Summary. In choosing instruments and procedures, it is preferable to collect information from a variety of sources and across a number of settings. A profile of outcomes is probably preferable to a single score. Tasks and procedures must be brief and easily administered. It is best to make choices based on a developmental rather than a psychometric perspective.

It is often difficult to distinguish between developmental screening and readiness tests. However, school readiness tests usually focus on skill acquisition and are product oriented, whereas developmental screening tests focus on the ability to acquire skills and are process oriented. Typically, readiness tests are used for class placement and planning of school curriculum and express a child's present level of skill performance rather than a child's developmental potential.

Examples of a number of commonly used screening instruments are given in Table 2. Evaluations concerning time and ease of administration and how comparisons of each with selection criteria are also provided.

Step 4. Choose Personnel and Plan Logistics

Personnel. It is important to choose a coordinator who has a thorough knowledge of normal development. Professionals who do not deal with preschoolers on a regular basis may have a tendency to underestimate the competence of youngsters of this age. The coordinator must also be able to function effectively within the system and work well with everyone involved in the program. A screening program's success depends a great deal on the cooperation of professionals, volunteers, parents, and various agencies who may be involved with preschoolers.

A school psychologist, early childhood specialist, and/or kindergarten teacher should be included in the planning team. In addition, personnel taking part in the actual screening must be carefully chosen and trained. Preferred characteristics for those persons include flexibility, organization, patience, thorough knowledge of procedures, confidence, ingenuity (who knows what will happen), experience and skill, and, perhaps most importantly, a good sense of humor. Do not discount the value of using parents and other volunteers. The authors have found fifth and/or sixth graders mature enough to be valuable "screening buddies." In this system, each preschooler being screened has his/her special buddy for the time actual screening takes place. These older students help to make sure each child progresses through all aspects of the screening. In addition, they are invaluable in entertaining those children not currently actively engaged in the screening process. This occurs when the number of children invited to participate exceeds the number of available stations or activity centers (more on these later).

Logistics. Outreach communication is essential in involving as many eligible youngsters as possible. Professionals should inform the community about the rationale for offering the program and its importance for children entering school. Additional information to be disseminated includes answers to

- Where and when will screening occur?
- Who will be screened?
- Who will perform the screening?
- Who will have access to the results?
- How will the results be utilized?

This information can be conveyed to parents and other agencies and service providers through special mailings, school newsletters, parent-teacher meetings, local newspaper articles, and special topic school programs. However, do not neglect personal contact with parents, which has been found to be more effective than mass media efforts. A special effort may be needed to contact parents whose first child is entering school. They generally are not attuned to local newspapers and other school information. They may be a little hesitant or just not know that such services are available. An important consideration during this phase is sensitivity by the school to parents.

Logistically, screening can be a nightmare unless carefully orchestrated. For example, the first time the authors screened youngsters in a particular school, the school nurse decided that this would be a good time for children to receive tuberculosis (TB) tests. After they had received the TB test, many children cried, setting off a chain reaction among those still waiting or going through screening. While it is an admirable goal for the school to ensure that children have adequate immunizations, screening is not the best time to offer those services.

Careful thought to physical arrangements and to progression through screening is also important. A first-time screening can make or break the program (as well as the program director and staff). It is amazing how little things make a difference. For mass screening such as that done during kindergarten roundup, a "station" type approach where each child is screened on particular tasks and then progresses to others seems to work best. This active system allows for children to move about physically and reminds examiners that attention spans are short. While some may question whether meeting a variety of screeners might be problematic for some "shy" youngsters, this system's advantages tend to override any disadvantages. As an example, important information may be gained if it is apparent that a youngster warms up more quickly with one examiner than another. Stations also allow for screeners to become "experts" in their screening procedures. This is extremely important because of the repertoire of behaviors common in this age group. The more practiced and automatic the examiner is the better. This arrangement also allows for better training of paraprofessionals and volunteer helpers.

If at all possible, it is a good idea to obtain, in advance, a list of youngsters being screened. The list should have the children's names as well as their birthdays. Each staff person participating in screening can then receive a list. Name tags, specifically designed for children, can be prepared ahead of time. The list and corresponding name tags make routing children through the system much easier. The authors have also found that rewarding each child with a sticker for each task completed is not only popular

TABLE 2
Commonly Used Screening Instruments

Instrument[a]	Time and Ease[b]		Age Range	Domains Evaluated	Standardization	Criteria Met[c]
				Screening Across Domains		
Brigance K & 1 Screen (1982)	10–20 min.	1	Kindergarten/ First Grade	Motor, auditory, visual, and 14 other domains	Field test; 14 states	4, 5
DDST (1975)	20 min.	1	Birth to 6	Personal-social, fine motor, adaptive, gross motor	Denver area only; white, black, Hispanic; children with disabilities excluded	2, 4, 5, 6
DIAL-R (1983, 1990)	20–30 min. Parent questionnaire is completed in 10–15 min.	3	2–0 to 5–11	Motor, concepts, language, family/behavior	National norms, 1980 census; white, non-white; Hispanic; children with disabilities included	1, 2, 3, 4, 5, 6
EPSF	60 min.	3	4 to 6	Receptive language, auditory, visual memory, visual discriminitation, fine motor, gross motor	Components of the battery include: The Peabody Picture Vocabulary Test–Revised, The Developmental Test of Visual Motor Integration, Draw-a-Person, Motor Activity Scale–Revised, The Preschool Language Scale. The first 3have natonal norms. There are no standardized data available on the battery	2, 4, 5
ESI (1988)	15 min.	1	4–0 to 5–11	Visual-motor, adaptive, language, cognition	465 from one urban community, all white; national norms in progress	2, 4, 5, 6
ESP (1990)	20–25 Min.	2	2–0 to 6–11	Cognitive/language, motor, self-help/social, Home, Health	National norms, 1990 census estimate; norms 1987–1988; children with disabilities included	1, 2, 3, 4, 5, 6
First STEP (1992)	15 min.	3	2–9 to 6–2	Cognition, communicaton, physical, social/ emotional, adaptive functioning	National norms, demographics, match U.S. census, 1,433 children. Norms available for 6-month intervals for each of seven age groups. Children with developmental delays accurately identified (72% to 85% accuracy)	1, 2, 3, 4, 5, 6
MST (1978)	20 min.	3	4–0 to 6–5	Right-left orientation, verbal memory, Draw-a-Design, number memory, concept grouping, leg coordination	MSCA national norms applied to MST; white, black, American Indians, Asians, Hispanics by race; Children with disabilities excluded	4, 5

(... Table 2, continued)

Instrument[a]	Time and Ease[b]	Age Range	Domains Evaluated	Standardization	Criteria Met[c]
MAP (1982)	20–30 min. 3	2–0 to 5–8	Sensory/Motor, cognitive ability, and combined abilities in five areas	National norms; 1,204 "normal" children; 86% white, 12% black, 2% othr; additional 90 children with disabilities included	2, 5
MPI (1979)	15–20 min. parent completes	4 to 5	Self-help, fine motor, expressive language, comprehension, memory, letter recognition, number comprehension, adjustment	The norms of the MPI were based on a sample of 360 white, suburban children ages 56–67 months. The hit rate of identification of children at risk for not having a successful school experience was 75%	2, 4, 5, 6
PDI (1984, 1988)	Untimed 1	3 yrs. to 6 yrs.	General development/ symptoms, behaviors	220 children in South St. Paul, Minnesota, who were in regular public school program	5, 6
MCDI (1974)	Untimes 1	6 months to 6 years	General development, gross motor, fine motor, expressive language, conceptual self-help, personal social	Norms compiled from a suburban sample distinctly different from the U.S. population	2, 5, 6
BDI (1984)	Untimed	Birth to 8 years	Personal–social, adaptive, motor, language cognitive	Research with the BDI is scarce and norms have not yet been obtained	2, 5
			Screeening of a Single Domain		
BBCS (1984)	20–30 min. complete scales 2	2–6 to 7–11	Basic concepts	Sample follows U.S. census. Total of 1,109 children. Southern and northern sections overrepresented	Screening Version not recommended 2, 3, 4, 5 Supplementary teaching materials
TABC (1988)	15_20 min. parent, teacher, clinician complete	3 to 7	Temperament (activity, adaptability, approach/withdrawal, emotional intensity, distractibility, and persistence)	National sample, overrepresented by Southeast	1 (if all forms are given) 2, 5

[a] DDST = Denver Developmental Screening Test–Revised. DIAL–R = Developmental Indicators for the Assessment of Learning–Revised. ESI = Early Screening Inventory. ESP = Early Screening Profiles. MST = McCarthy Screening Test. MAP = Miller Assessment for Preschoolers. PDI = Preschool Development Inventory. MCDI = Minnesota Child Development Inventory. BDI = Batelle Developmental Inventory Screening Test.

[b] Ease of Administration: 1 = easier to administer than most preschool instruments; 2 = administration ease is average as compared to others; 3 = more difficult to administer and score than many.

[c] Criteria are designed to aid in the selection of appropriate instruments for the reader's specific task.

1. Includes information about behaviors across a variety of environmental settings and from a variety of sources.
2. Profile of outcomes is available.
3. Evidence for adequate standardization, psychometric properties.
4. Accepted by primary users.
5. Contains brief tasks and procedures.
6. Focuses on developmental rather than readiness tasks.

TABLE 3
Practical Activities for Parents to Help Work with Young Children

Area of Weakness	Suggested Activities
Language Skills	1. Talk with your children, not just to them.
	2. Ask open-ended questions.
	3. Read to your children each day.
	4. Slow down speech so children will understand sounds and words.
	5. Discourage baby talk.
	6. Help children categorize objects by color, shape, size, texture, use, etc.
	7. Teach children to use functional language.
Gross Motor Skills	1. Encourage outdoor play with running, hopping, and jumping activities.
	2. Engage children in throwing and catching of objects (bean bags, balls, balloons).
	3. Have children walk on a line to help balance.
Visual Motor Skills	1. Provide opportunities for children to work with clay or play dough.
	2. Practice using scissors and paint brushes.
	3. Manipulate puppets.
	4. Practice buttoning, zipping, tying, tracing, and coloring/drawing.
Auditory–Memory	1. Have children identify common sounds with their eyes closed.
	2. Give children a series of two- or three-part instructions orally.
	3. Have children reproduce tapped patterns.
	4. Encourage listening and following oral directions.
Basic Concepts	1. Let the children practice locating parts of the body.
	2. Have children complete partially drawn figures.
	3. Work with colors, one at a time.
	4. Begin letter recognition, starting with upper case first.
	5. Point out letters on signs and books.
	6. Cut out letterforms; have the children trace and color letters.
	7. Introduce numbers with activities similar to those for letter recognition.
	8. Model shapes with clay; have the children trace and color shapes and cut shapes from different materials.
	9. Reinforce through conversation concepts such as size, texture, quantity, time, and social relationships.

with the children but provides a quick check of whether they have completed each task. It is helpful, and fun, to use stickers that correspond to the stations. For example, a particular favorite of these authors is the sunglasses sticker to use for visual screening.

In establishing the routines of screening, it is wise to keep in mind that many of the normal characteristics of preschoolers call for special "accommodations." Parents may need to stay in the room or close at hand. Extra time may be needed to establish rapport and examiners should be cautioned to allow children to warm up to the situation rather than coming on too strong. Limits need to be set and gently, but firmly, reinforced. Preschool children need plenty of reinforcement and tangible reinforcers produce good results. However, reinforcement must focus around the effort rather than correctness of answers. Compared to school-age children, preschoolers respond better to shorter testing periods and more frequent breaks. Providing for adequate space to move around and play is essential. It is a great help to have a number of active games and videotapes available for children who are waiting or between stations.

When screening is connected to kindergarten roundup, orientation for the parents can be scheduled during the time when their children are being screened. This usually consists of presentations by the principal, kindergarten teacher, latch key coordinator, and other professionals with whom the children may be involved. Parents also fill out rating scales and information sheets that become part of the

FIGURE 1. The role of the parent: You are very important!

Consistently	support the behavior you ask your child to demonstrate.
Read	to your child often.
Experience	and share short trips with your child. The zoo, store, and a farm are good places to begin.
Ask	and answer questions about what your child sees or does.
Talk	to and with your child often.
Encourage	your child to carry out simple duties at home.

Supply	your child with crayons, paper, and scissors to be used in a constructive manner.
Understand	good and poor behavior, and explain limits when it is necessary.
Count	and add small objects with your child.
Create	an interest in doing things for fun.
Encourage	your child to speak distinctly.
Sing	and play children's songs. Use records and help your child select TV programs with music.
Show	your love and affection for your child for no apparent reason other than for being your child.

data to be analyzed in Step 5. Some programs encourage parents to actively participate with the child during screening. In fact, some procedures allow for screeners to evaluate parent-child interaction during an instructional task. When parents are observing in the room where screening occurs, it may sometimes be better to have them sit out of the direct line of vision of the child. On the other hand, parents should never be *required* to observe and in some cases may have to be asked not to observe if anxiety on the part of either parents or child is observed.

Step 5. Analyze Data within and across Contexts Comparing Data from and about Various Sources

Many available screening instruments provide information about the desired areas of interest, although not every instrument will sample behavior from each of the domains. Although there may be a tendency for some to rely primarily on scores, it is important when working with preschoolers to look beyond scores. Other relevant pieces of data must be included in interpretation of screening results for young children. In some cases it may be more important to recognize the *how* and *why* of a child's performance than in scores per se. Examiners must not only be skilled in administering tests but also be good observers and interpreters of children's behaviors. These observations then become part of the data analyzed during this step. Poor performance may be the result of many factors, including the possibility that a child does not possess the skill. However, with these youngsters, it may be just as possible that the lack of performance is due to any one of several other factors such as attention span or lack of understanding about the parameters of the task.

Interpretation of scores from screening instruments should include consideration of other data collected. One specific example illustrating the importance of auxiliary data is a phenomenon the authors have often noticed on the *Bracken Basic Concepts Scale*. It is not unusual for children to score fairly well in the average range on most of the basic concepts scales except for the School Readiness Composite (SRC). This composite consists of five scales which tap at such things as letter and number recognition, shape recognition, and the like. Performance on these tasks seems to be fairly vulnerable to previous experiences; that is, they are tied more closely to actual experiences, such as exposure to preschool or enriched home environments than the other tasks. The net effect is that low performance on the SRC with average or above average performance on the other scales may indicate that the child has not had adequate training and/or experiences. On the other hand, if this same pattern exists for children who have had preschool experiences and adequate environmental stimulation, the chance is greater to develop the types of school-related problems connected with learning disabilities. This interpretation is very dependent upon the other information garnered about the child. Of course, one could go on forever with specific instances of where interpretation based on all the available data is important. However, the hypothesis-testing framework that school psychologists use in their assessment procedures provides a good structure for analysis of these data as well.

One goal of analysis must be to determine which children to refer for more complete assessment. A three-tier system has proven useful: Children who have obvious problems can be referred for further evaluation; those who have some delays or difficulties may be rescreened or watched for problems, and those who have few or no problems are "passed."

Step 6. Provide Feedback for Parents and Recommend Experiences Designed to Enhance the Child's Chances for Success

Parents should receive feedback about their children's performances. Whether children are progressing normally or display weaknesses, parental follow-up should be prompt. Parents of children designated to be rescreened or referred for further assessment should be contacted personally and individually. An important consideration during this time is making parents aware that screening results are not final diagnoses or outcome measures for this child's development.

Even normal development may be inconsistent. Through screening, various strengths and weaknesses among different domains may be identified. Often parents are unaware of exactly what they can do to help their children. Practical and easy activities for parents to do with their children are given in Table 3 and Figure 1. Remember, parents may be the most important teachers their children will ever have.

Step 7. Evaluate and Revise Procedures Where Changes Could Result in More Efficiency, Greater Communication, and/or Smoother Integration of Systems

Only if we are willing to learn from what we have done, can we improve our practice. What works for one school psychologist may not work for another. New instruments and procedures are developed all the time, and programs and philosophies change. In order to continue having the best program possible, periodic review is necessary. A debriefing session as soon after screening as possible is especially helpful. Consider including several parents in this session to solicit their impressions as well as those of staff.

SUMMARY: PUTTING IT ALL TOGETHER

The application of a comprehensive model for preschool screening should not result in simply labeling of children. Instead, these procedures should aid teachers and committees in the planning of curricula and developmentally appropriate programs for young children. Teachers need to convey clearly to parents the importance of program development and the ways information obtained through screening can aid in this process. Models that incorporate the relationships between the child and the various settings within which he or she interacts represent an ecological perspective (Paget & Nagel, 1986).

All the suggested components recommended in the formation of a screening program require advance planning. Meisels (1989) suggests making the following decisions prior to the formation of a screening program:

1. Determine funding sources.
2. Identify a coordinator for screening program.
3. Set up a screening planning and implementation committee.
4. Determine the purposes and goals of the screening program.
5. Identify the population of children to be screened.
6. Select the appropriate screening instruments and procedures.
7. Arrange the location and time of screening.
8. Arrange the medical examinations, vision and hearing tests.
9. Engage parent and community cooperation for child identification.
10. Recruit and train screening staff.
11. Conduct in-service training for kindergarten and other early childhood teachers.
12. Implement screening program.
13. Request information from teachers and parents/caregivers.
14. Monitor all components of the program.
15. Communicate results and impressions with parents.
16. Provide recommendations to parents if necessary.
17. Notify assessment teams of follow-up on individual children.
18. Evaluate screening program effectiveness.

ANNOTATED BIBLIOGRAPHY

Bracken, B. (Ed.). (1991). *The psychoeducational assessment of preschool children.* Boston: Allyn and Bacon.
This comprehensive book on assessment of preschoolers has a single chapter devoted exclusively to screening. However, this chapter's authors recommend this book as a definite inclusion in the professional library because it addresses so many important issues in working with youngsters in early childhood.

Bagnato, S. J., & Neisworth, J. T. (1991). *Assessment for early intervention: Best practices for professionals.* New York: Guilford.
Best available treatment of alternative models for assessment, especially curriculum based issues. Provides a philosophical model yet has much to offer in the way of implementation and practical aspects. While a majority of the book deals with assessment in general, there is an entire chapter devoted to screening.

Harrison, P. L. (1992). Planning and evaluating preschool screening and assessment programs. *Assessment News, 2*(3), 1, 8–11.
A short article that provides a succinct overview of the whole process. Many important issues are outlined and discussed including reasons for assessment/screening, usefulness of early intervention, inherent dangers in identification, and discussion of limitations of instrumentation often used.

Lichtenstein, R., & Ireton, H. (1984). *Preschool screening: Identifying young children with developmental and educational problems.* Orlando, FL: Grune & Stratton.
This little book probably still remains *the* classic in this area. A book that must be read by anyone involved in implementation of a screening program. Includes information on parent involvement, screening instruments, and establishing programs.

Meisels, S. J. (1989). *Developmental screening in early childhood: A guide* (3rd ed.). Washington, DC: The National Association for the Education of Young Children.
A practical, hands-on treatment of screening. Deals with many of the nuts and bolts and procedural issues connected with implementation. Copy of the *Early Screening Inventory Parent Questionnaire* is included.

Best Practices in Implementing Intervention Assistance Programs

Roslyn P. Ross
Queens College of the City University of New York

OVERVIEW

Intervention assistance programs go by a number of names in the schools where they are found (e.g., prereferral intervention, prereferral consultation, mainstream assistance teams, teacher assistance teams, teacher support teams, student assistance teams, instructional consultation teams). All are support systems for solving problems within the regular classroom. They are intended to provide immediate assistance to students and teachers, to enhance the ability of teachers to effectively serve difficult-to-teach students within regular classrooms, and to reduce inappropriate referrals to special education. They are often called prereferral programs because they are used to assist teachers in generating and implementing intervention strategies *prior* to seeking referral for consideration of a more restrictive placement. The model of service delivery common to intervention assistance programs is consultation; in this respect, they do not introduce a new type of service delivery. Readers interested in implementing such programs also will find much that is useful in the chapters on School Consultation and Behavioral Consultation in this volume.

Intervention assistance programs first began to be described in the literature in the late 1970s and early 1980s (e.g., Chalfant, Pysh, & Moultrie, 1979; Graden, Casey, & Christenson, 1985). They represent the most concerted and organized effort to date to correct a number of problems associated with service delivery under PL 94-142, The Education for All Handicapped Children Act of 1975. Too often, the only pathway to service for students having behavioral and learning difficulties is a "referral-test-place" sequence. This has resulted in overreferrals to special education (Research for Better Schools, 1986) and misclassification of students as disabled. It also has resulted in identification procedures that are costly and time consuming. One-half of all school psychologists, for example, devote more than 40% of their time to identification for learning disabilities, with about one in five devoting more than 60% of their time to this activity (Ross, in press). Despite their cost, current diagnostic procedures, which emphasize standardized testing, usually yield little more than placement–no placement decisions. They must be followed by alternative types of assessment to develop intervention plans. These factors have led many professionals to question the amount of time devoted to "gate keeping" in our current service-delivery system as well as the particular gate that is being kept.

Intervention assistance programs propose consultation as an alternative framework for delivering service. Although the role of consultation is not new in school psychology, its implementation often depends upon the initiative of a particular individual and may fade away when that person leaves (Graden, Casey, & Bonstrom, 1985). A number of the programs currently being developed are attempts to implement a school-wide consultation service model. These programs often include teams of professionals, all of whom are trained in consultative, problem-solving methods. Team composition is a variable that distinguishes two types of intervention assistance programs currently in existence. One type, the one that school psychologists are involved in, has multidisciplinary teams. The second type is composed solely of regular classroom teachers, although others may be asked to participate when necessary. Teacher Assistance Teams, problem-solving groups composed of regular classroom teachers, were originally introduced as an alternative to traditional in-service training in the early 1970s (Chalfant, Pysh, & Moultrie, 1979). They emphasize teacher initiative, communication, and effective decision making. Teacher empowerment through self-help is an underlying assumption.

Clearly, intervention assistance programs have much to recommend them. Pugach and Johnson (1989a) argue they are an extraordinarily progressive concept and a clear improvement to legislated practice because they (a) remediate unnecessarily restrictive parts of PL 94-142; (b) appropriately redirect special education resources toward the immediate solution of problems in the classroom; (c) provide resources for students not identified as disabled; (d) are consistent with important task-force recommendations for reforming both the operation of schools and the preparation of teachers (e.g., the need for building-level responsibility shared among professionals in the schools, encouragement of collaborative problem-solving characterized by collegial professional relationships, increased professionalism for classroom teachers). You may well recognize the consonance of these goals with those of mainstreaming and the Regular Education Initiative (Will, 1986).

The great appeal of intervention assistance programs is shown by the extent to which they have been endorsed by state education agencies. A survey conducted in 1987 by Carter and Sugai (1989) indicated that prereferral interventions for students suspected of having a disability were required by 23 state education agencies and recommended by 11. Information is lacking, however, on how local educational agencies actually implement states' recommendations; the prevalence of such programs within schools is unknown.

Carter and Sugai (1989) noted that prereferral intervention became a common component of state educational agency policy even before there was much empirical support for its effectiveness. Currently, promising evidence indicates that intervention assistance programs can reduce the number of students referred for formal assessment and then placed in special education *if* there is appropriate administrative support, sufficient time and resources invested in the program, staff willingness to be involved, and well designed interventions faithfully executed (e.g., Chalfant & Pysh, 1989; Graden, Casey, & Bonstrom, 1985; Fuchs, Fuchs, & Bahr, 1990; Fuchs, Fuchs, Bahr, Fernstrom, & Stecker, 1990). The programs also can yield high teacher and student satisfaction and appear to improve teacher attitudes toward and tolerance of students experiencing difficulties. Outcome studies generally show implemented strategies can produce desired student performance, but this is frequently assessed by having the same person implement the strategy and rate its perceived effectiveness in the absence of data-based measures. Interventions have tended to focus more on management and maintenance of student behavior (e.g., work habits, classroom and interpersonal behavior) than on academic performance. Chalfant & Pysh (1989) suggest that this will change with time. They report observing that as a program matures, teachers shift from seeking assistance for behavior management problems, usually first priority issues, to seeking assistance for academic skill problems.

An adequate data base does not yet exist to evaluate the extent to which intervention assistance programs lead to increases in academic skills, class management skills, teaching skills, consulting skills, and professional collaboration. This is not so surprising given the time and effort that first must go into developing a program and the extreme difficulties that doing research in this area entail (see, e.g., Fuchs, Fuchs, Dulan, Roberts, & Fernstrom, 1992; Rosenfield, 1992).

Despite these difficulties, we do have "encouraging notes on preliminary findings" (Sindelar, Griffin, Smith, & Watanabe, 1992, p. 245) to add to the enthusiasm found in the literature and at the state education agency level. Currently, the efforts of practitioners and researchers, who work in the area, are being devoted to identifying and creating the conditions necessary for successful implementation. These conditions as well as the obstacles to creating them are given major attention in the next section on basic considerations. Following this, guidelines are presented for best practices in developing a program and providing intervention assistance.

BASIC CONSIDERATIONS

Controversial Issues

The emergence of intervention assistance programs presents psychologists with exciting opportunities to focus more of their efforts on trying to help resolve student problems when they first start. Most school professionals would agree that this is a worthy goal. Controversy arises, however, from the fact that intervention assistance programs also have come to represent a strategy for implementing educational reform. This reform involves changes in the way resources are deployed as well as changes in the way educational professionals function and relate to each other. It should come as no surprise, therefore, that there is considerable debate in the professional literature about reform issues and that these issues are likely to surface whenever an intervention assistance program is considered. Differences arise on how comprehensive the reform effort can be and how professionals should collaborate.

Who owns mainstreaming? As Davis (1989) points out, mainstreaming was not the idea of general education teachers, but they own the potential burden of instructing more difficult-to-teach students. Usually, they must do so without appropriate reductions in teacher–student ratios. It has been argued (e.g., Friend & Cook, 1990; Evans, 1990) that mainstreaming is unlikely to become enthusiastically owned by general teachers if it is oversold, underfunded, unrealistically expands roles and responsibilities, or is directed by others. Questions about the advisability of reducing or eliminating some traditional special educational services, without better evidence of its potential for success, are raised by other educational professionals and community groups as well.

Furthermore, as Friend and Cook (1990) point out, general and special educators historically have had different overriding goals for their students. Special education's requirement for extensive individualization (of instruction and mastery standards) may well conflict with regular education's goal of getting a relatively large number of students to master specified content within a specified time period. Requiring extensive individuation also is incompatible with other current educational reform proposals. Concern with the quality of public education and teacher training has lead to calls for placing greater emphasis on achievement. This call would have teachers increasing homework and stepping up the educational pace for their students.

Who owns prereferral intervention? Even when education professionals agree upon the need to find ways to maintain difficult-to-teach students within the classroom, they may disagree upon whose purview this is or who should be doing the consultation. This disagreement may take the form of recommending different kinds of support systems.

As stated earlier, intervention assistance programs currently fall into two types based on team composition, and team composition tends to determine who the consultant is. Those who advocate a multidisciplinary team, where the consultant more often than not is a specialist, often stress the collaborative nature of consultation (see, for example, Graden, 1989; Idol, Paolucci-Whitcomb, & Nevin, 1986). Those who advocate teacher teams, where the consultant is a teacher and specialists are invited to participate when necessary, may question whether consultation between general educators and special educators or psychologists can be truly collaborative with equal value given to each person's input. Pugach and Johnson (1989a, b) for example, argue that prereferral consultation as it is commonly practiced involves classroom teachers receiving assistance from specialists; it is an expert, rather than a collaborative, model of consultation that is implemented, despite assertions to the contrary. The danger that this presents, according to Pugach and Johnson, is that it reduces independence on the part of classroom teachers and subverts teacher empowerment. They contend that true collaboration, involving parity or equal value given to each person's input, can only exist when general educators help one another. They further argue that because mainstreaming is part of the general teaching environment, teachers, rather than special educators, should own the resources for problem solving (time and training) that prereferral structures grant. "In the context of prereferral interventions, the proprietary role specialists now play only defers a consideration of what constitutes the proper boundaries of special education in the schools" (Pugach & Johnson, 1989a, p. 225).

Prescriptive or collaborative consultation? This issue involves questions about the popular view that consultation should be collaborative, that is, involve a reciprocal arrangement "that enables people with diverse expertise to generate creative solutions to mutually defined problems" (Idol, Paolucci-Whitcomb, & Nevin, 1986, p. 1). (The reader who is interested in a discussion of conditions necessary for collaboration is referred to Friend & Cook, 1990.) Fuchs, Fuchs, Bahr, Fernstrom, and Stecker (1990), for example, argue that there is a justifiable place for prescriptive approaches to prereferral intervention and school consultation:

> In schools in which stress is high, expertise in consultation is low, and consultation time is non-existent, prescriptive approaches appear better suited for success than collaborative ones. We have no doubt that, in different situations, more collaborative approaches may represent a better choice. . . . The nature of consultation activity should be determined more by the circumstance in which consultants find themselves than by an a priori belief system. (p. 511–512)

Fuchs et al. (1990) drew these conclusions from their well-researched effort to implement Mainstream Assistance Teams (MAT), a behavior consultation model with specialists as consultants. At the end of the first year of the program, which followed a multidisciplinary, collaborative model, they found that in-class interventions produced unimpressive results. During the second year they changed to a prescriptive model. MAT consultants and teachers selected among a small group of carefully detailed interventions with prescriptive instructions; multidisciplinary teams no longer were involved in the process. Results were much more impressive. Fuchs et al. (1990) reported:

> [At the end of year 1] many teachers complained they had insufficient time for the give-and-take nature of collaborative problem solving. Instead, they wanted helpful suggestions. In contrast, during debriefings and on questionnaires administered after more directive Year 2 activity, teachers from the same school district expressed satisfaction with the MAT interventions and consultation process. No one described the project experience as coercive or implicitly denigrating of his or her knowledge or skill. (p. 511)

While prescriptive plans appear to increase the efficiency of implementation, questions have been raised about whether such "packaged" plans may deprive the staff of a necessary sense of ownership and disappear when the program designer departs (Rosenfield, 1992).

Potential Obstacles and Disincentives

Any decision to adopt a program as a solution to identified problems involves weighing relative advantages and disadvantages. Factors that may be perceived as potential disadvantages of an intervention assistance program follow. These potential disadvantages or disincentives can be thought of as obstacles to successful implementation that need to be overcome through creative problem-solving.

- *Loss of funding resulting from reduced student enrollment in special education classes.* Successful prereferral intervention threatens a loss of state funding based on the number of students serviced within special education. It certainly cannot be rewarding for school district administrators to contemplate finding themselves with significantly less funds to accomplish the same goals with difficult-to-teach students, albeit in a less restrictive environment. Models have been proposed for compensating school districts for implementing effective programs (e.g., Fry, 1990; Idol, 1988); appropriate financing is critical.
- *Cost of intervention assistance programs.* Considerable resources have to go into starting intervention assistance programs if they are to have a chance to succeed. Time needs to be appropriated for the process and workloads have to be adjusted appropriately. Personnel need training in consultative problem-solving procedures. Given current estimates that it takes about 3 years to implement programs (Chalfant & Pysh, 1989; Fullan, Miles, & Taylor, 1980; Ponti, Zins, & Graden, 1988), some districts may be reluctant to support a program whose promised cost containment will take some time to realize. Many of the programs described in the literature have coped with this problem by obtaining special start-up funding in the form of grants from state or federal agencies. Gifts from individuals, corporations, or foundations also may be solicited.
- *Scaled-down costs may involve scaled-down expectations.* It is reasonable to expect that gains in professional productivity can result from investing in training and improving organizational structure. It seems less realistic, however, to expect that problem-solving skills of education professionals will increase enough to bear the entire cost of providing a full range of services to difficult-to-teach students in less restrictive settings. The cost-containment expectations for intervention assistance programs are at odds with expectations that "the public school [is] responsible for remediating virtually the entire range of physical, cognitive, and emotional conditions that can affect students" (Evans, 1990, p. 73). One or the other of these expectations may have to be scaled down.
- *Loss of jobs.* Part of the reason for the popularity of prereferral intervention is that it promises to contain the burgeoning costs of special education. Many special education and special services professionals fear that, if successful, this may translate into lost jobs rather than new opportunities for better service delivery. Similar fears may arise if prereferral activities are perceived to lead to a redeployment of scarce resources from special education to regular education; protecting one's turf may take precedence over building collegial problem solving under such circumstances. The development of a more efficient and effective service delivery system, however, can serve as an impressive validation of the effectiveness of the service providers. This, in turn, could lend credence to the importance of providing financial support for other services.
- *Changed job roles and responsibilities.* While this may be described as an advantage in the reform literature, it does not always feel like one to professionals who have spent much time and effort to develop certain competencies. Even when convinced of the need for change, they may find it unpleasant to replace (temporarily, though it may be) a feeling of mastery with the inevitable anxiety and uncertainty that accompanies learning new skills and ways of functioning. Inservice training and ongoing support systems for participating staff are essential components of any intervention assistance program.
- *Increased job responsibilities.* If the demands of the program are added to the demands of traditional roles (e.g., caseloads remain the same, individualized instruction for some students is added to the regular teaching environment, no release time is given teachers for the problem-solving process), this can be quite a disincentive and barrier to successful implementation. Indeed, a shortcoming frequently reported by participants evaluating their prereferral program is that they lacked enough time to consult. Sufficient resources have to be marshalled to make sure that participants are not overloaded with work.
- *Commitment to special education services under PL 94-142.* While most education professionals acknowledge problems connected with service delivery under PL 94-142, many may believe that the advantages outweigh the disadvantages or alternatively that it is premature to restructure schools to eliminate some traditional special education services without better evidence of the effectiveness of prereferral intervention and mainstreaming. The benefits of change may be perceived as doubtful or not worth the risks. The prereferral model may be perceived as withholding beneficial special education services to students. Parents too may pressure for special education services under PL 94-142. Continuing research is needed to settle what are essentially empirical questions about the relative effectiveness of different service delivery systems.
- *Commitment to other programs.* New program implementation may already be taking place or a school may not have enough resources to introduce additional programs. Additionally, if the new program (e.g., curriculum reform) reflects a proposed solution for the same problems that inter-

vention assistance programs address, the one already being implemented may be seen as a more appropriate solution.

- *More bureaucracy.* An intervention assistance program runs the risk of becoming another layer of bureaucracy. If too complex, it may detract from the immediate resolution of problems.
- *Resistance to change.* This disincentive does not refer to legitimate opposition to change. Rather, it refers to the natural tendency of people to protect themselves from uncomfortable feelings of anxiety and uncertainty, typically stirred by changes to anything perceived as important, by resisting such change. Examples of particular dangers that prereferral programs may represent are (a) threats to esteem because of implied failure of previous efforts or because of shifts in focus from child-as-the-problem to instructional and organizational factors, (b) decreases in self-esteem that inevitably accompany learning new skills, (c) loss of status associated with needing help, (d) threats to independence and control, and (e) threats to job security. Certainly, people differ in the ease with which their anxiety or defenses are stirred, but such reactions are to be expected. Awareness of the ongoing concerns of participants needs to be maintained so that concerns can be addressed through training and support processes. Readers interested in an indepth discussion of resistance and strategies for working with resistance are referred to Margolis, Fish, and Wepner (1990) and Zins, Curtis, Graden, and Ponti (1988), Chapter 9.
- *Poorly conceived plans.* This is a rather obvious disincentive and ways to avoid it will be discussed in the best practices section of this chapter.
- *Well conceived plans.* This is a not so obvious disincentive. Well conceived plans include a strong evaluation component (e.g., whether the model is actually being implemented as designed, effectiveness of staff training, effectiveness of intervention assistance). Rosenfield (1992) describes why this is likely to be seen as a disincentive from the point of view of the school:

> The intolerance of school personnel for extensive research procedures is legendary. Even with excellent working relationships, there were many kinds of research designs that were not possible for [Instructional Consultation] IC-Team . . . because the school culture does not find research a meaningful use of its precious resources of time and personnel. (p. 43)

Rosenfield recommends that research in school settings be kept short, cheap, and simple.

Resources Needed

Now that the long list of potential obstacles that may have to be handled is past, the reader may well wonder what the bottom line is. What resources are needed to give one a fair chance of doing useful intervention assistance? This next section identifies resources (or facilitators) mentioned consistently in the literature (see, e.g., Chalfant & Pysh, 1989; Graden, Casey, & Bonstrom, 1985; Idol & West, 1987). A subsequent section focuses on the specific skills that a practitioner needs to become involved in different aspects of intervention assistance programs.

- *Planning, patience, persistence, and perspective.* Developing and implementing intervention assistance programs is a complex and demanding process. This message is sounded time and again in descriptions of the process found in the literature. A great deal of careful planning is required to set the stage for change. Unforeseen challenges must be faced during implementation which require recycling to earlier stages of problem solving and program formulation. It has been reported (Chalfant & Pysh, 1989; Rosenfield, 1992) that it takes about three years to get programs implemented and another year or two for them to become institutionalized (an integral, accepted, and effective part of a building system).
- *Time to consult.* Consulting has to be a legitimate activity, not something squeezed in for a few minutes in the hallway, or whenever time can be spared from regular responsibilities. Insufficient time to consult is one of the most cited criticisms in program evaluations. Teachers need to be given release time with coverage for their classes if they are to make use of consultation services. Consultants need schedules which make them available during appropriate times. Idol (1988) describes a number of scheduling possibilities that have been used successfully for varying grade levels. She also gives guidelines for determining appropriate caseloads for consultants, including teachers, who have both direct and indirect service delivery responsibilities.
- *Administrative support.* The need for substantial administrative support is invariably included in program descriptions and evaluations. The foremost need is administrative support in the form of providing time for personnel to consult on a regular basis (e.g., Chalfant & Pysh, 1989). Administrative support also takes the form of providing policy initiatives for prereferral intervention, encouraging and publicizing program efforts, engaging in thoughtful planning, and mobilizing resources. Whether administrative support should take the form, as it has in some programs, of leading team problem-solving meetings remains controversial. Professionals may be reluctant to reveal problems to a principal who also has to evaluate their job functioning.

BEST COPY AVAILABLE

- *Staff development and training.* An obvious need is staff with good consultation skills. Practitioners who already have these skills represent an invaluable resource. However, staff development is consistently included as a major, needed component of intervention assistance programs. All faculty need an orientation to the concepts and techniques of the program. Staff who elect to participate in the program need considerably more training, not only to enhance (or develop) their consultation skills but to function effectively in teams. Without training, teams tend to be inefficient and ineffective (Hayek, 1987; Schram & Semmel, 1984). Training for skill development requires opportunities for observing of effective practice, feedback, and guided practice. It is an ongoing process and provides staff with continued technical assistance and support systems (e.g., opportunities for peer supervision and for networking) after the period of initial skill development.
- *Faculty support.* Without sufficient faculty support, there can be no program. Indeed, program effectiveness is often measured in terms of the willingness of faculty to be involved. This resource has to be cultivated through involving faculty in needs assessment and planning, providing orientation to the program, providing training and appropriate support for change, allowing for voluntary participation, and coming through with perceived benefits.
- *Parent support.* Outcome studies have tended to ignore the role played by parent support, so little empirical data exist demonstrating its importance. However, most program developers consider it quite important and devote effort to gaining the support and sanction of all interested parties, including parents. This is done through providing information at orientation meetings, involving representative groups in planning, sharing information on an ongoing basis, and coming through with perceived benefits.
- *Financing.* Funding is particularly crucial during the start-up period. There are expenses for planning, training, inservice presentations, release time to consult, evaluation, and publicity. These expenses precede potential cost savings. Funding sources have included bootstraps, local schools, school districts, bureaus of cooperative educational services (BOCES), state education agencies, the federal government (e.g., Office of Special Education Programs), and private foundations. These are temporary solutions and workable funding plans for ongoing programs need to be developed at the state level.

Skills and Knowledge Needed

School psychologists may function in many different roles in intervention assistance programs. They may be involved in program development, program oversight, team leadership, team problem solving, and provision of individual consultation services. It is hoped they are not attempting to function in all of these roles at the same time.

These roles all require knowledge of and skill in engaging in the various phases of a problem-solving consultative process. Idol and West (1987) describe the consultation process as involving both a communicative/interactive component and an underlying knowledge base. The first component refers to the good interpersonal and communication skills that must be in place to engage clients in the process. The second component refers to having something of value to share once clients are engaged. Psychologists draw on the wide knowledge base required to be a school psychologist in the first place for this "something of value to share." Special emphasis, however, is placed on some knowledge domains.

Most obviously, a knowledge of systematic steps to be followed in a problem-solving process is required for all consultation. (These steps are described later in the chapter and are fully detailed in other chapters on consultation in this volume.) Intervention assistance programs additionally require a particularly strong knowledge base in the domain of effective classroom intervention technology. In addition to the many relevant chapters in this volume, the reader may consult Cohen and Fish (1993), Martens and Meller (1990), and Shapiro (1988) for information on intervention technology and Gresham (1989) for information on treatment integrity.

An analysis of existing intervention assistance programs by Idol and West (1987) indicated a common requirement for knowledge of and skills in assessment focused on curriculum-based assessment and diagnostic/analytic teaching. Rosenfield (1992) stresses that this should also include being able to monitor student progress by providing data-based measures (e.g., graphing). Intervention assistance programs seem to rule out the possibility that assessment based on standardized testing is useful in analyzing problems at a prereferral stage; such assessment is restricted to formal evaluation procedures associated with special education consideration.

Knowledge of systems theory ad change techniques is included as an important requirement by those who propose that consultants function as change agents at the system or school level (e.g., Zins et al., 1988). This is the role assumed by consultants during program initiation and development. Some interesting evidence suggests that gender-associated attitudes about engaging in leadership behaviors may be as influential, if not more so, as possessing requisite knowledge in determining whether consultants attack problems at a system level. Conoley and Welch (1988) found, from their analysis of consultation logs, that young, female psychology trainees concentrated on individual problem solving, mainly with same-sex consultees of relatively low status in the organization. In contrast, young male trainees (with the same training and qualifications) were more likely to be involved with administrative staff, often male, and tended to use more risk-taking or systemic models of consultation. Thus, positive attitudes about exhibiting leadership behaviors and relating in an authoritative manner with (primarily male) administrative personnel have to be added to the skills and knowledge necessary to initiate and develop intervention assistance programs. Women who are concerned that they may be disadvantaged in this regard will find the Conoley and Welch (1988) article of interest.

Finally, psychologists who assume team leadership roles require knowledge of group dynamics and skill in facilitating team problem solving. The interested reader is referred to Arends and Arends (1977) for their discussion of task and maintenance functions in leading groups. All members of problem-solving teams need knowledge of effective teaming strategies; training in teaming strategies should be part of program development.

BEST PRACTICES

Problem solving is the essential characteristic of consultation and intervention assistance programs. A number of steps are followed systematically in dealing with problems whether they concern individuals or systems. Bergan (1977) describes the steps as including problem identification, problem analysis, plan implementation, and plan evaluation. Gutkin and Curtis (1982) further divide the stage of plan implementation into generating alternative strategies through brainstorming, evaluating alternative strategies, clarifying implementation procedures and responsibilities, and implementing the strategy.

Some of the intervention assistance programs in existence favor the behavioral model of consultation which tends to focus on developing interventions for individuals or small groups of students. The interventions thus developed are based on social learning theory and behavior modification and might involve, for example, increasing or decreasing the frequency of a targeted behavior. Other programs favor a process model of consultation which tends to focus on organizational analysis and interactions among people in work groups — the teacher's skill in handling a group of students, for example, rather than on the student's behaviors per se. Interventions are based on research on small groups, organizational effectiveness, and social psychology, and are designed to restructure the setting so that individuals can make progress (e.g., improving the teacher's skill in pacing instruction in order to increase students' academic engaged time; restructuring a management system within the school to be more collaborative).

A third model, mental health consultation, focuses more on discerning what is blocking the teacher's problem-solving skills (e.g., lack of knowledge, skill, self-confidence, or objectivity). Mental health consultation has its roots in psychodynamic psychology which includes an interest in unconscious dynamics. Interventions might involve providing information (e.g., recommending how the teacher should deal with a student, arranging for inservice training), modeling skills, providing support and reassurance for blocks coming from lack of self-confidence, or helping the consultee improve objectivity through techniques which Caplan (1970), the developer of this approach, called theme-interference reduction and indirect confrontation. Consultants also pay attention to organizational realities and group difficulties. According to Conoley and Conoley (1988), the mental health consultation model is foreign to the style of most school-based consultants and least likely to be accepted by school organizations. Indeed, intervention assistance programs described in the literature do not appear to be favoring this model.

The reader interested in learning more about how the different models effect the routine activities and problem-solving formulations of the consultant should read the analysis by Conoley and Conoley (1988), which served as the basis for the preceding description. West and Idol (1987) also present an excellent review of consultation theory.

Few detailed descriptions of how programs were actually developed and implemented currently exist. Notable exceptions are the handbook by Fuchs and his colleagues and the guide by Zins and his colleagues, both listed in the annotated bibliography. As program development proceeds, handbooks are likely to become more available; some state education agencies (e.g., Ohio) seem to be developing them. Professionals who are involved in this early stage will find it helpful to share information with their colleagues informally and at professional meetings. The overview of practices that follows is based on a review of the literature.

Program Development and Initiation

During this step, decisions must be made about the need for an intervention assistance program, as well as the type of program to adopt, resources must be mobilized and committed, and an operating plan for implementing the program must be developed (Rosenfield, 1992; Zins et al., 1988). The tasks often overlap and influence each other. Talking to school members about whether they see the need for intervention assistance, for example, also may have the effect of interesting some in working on perceived problems — certainly a valuable resource to mobilize during problem clarification and analysis.

Deciding to adopt a program. An intervention assistance program imposed just because someone wishes to have consultation services available or has a vision of change not shared by others, starts off on very shaky grounds. Efforts have to go into clarifying the need for a program and the school's willingness to consider one. Talking to colleagues is one of the ways of starting this effort. Zins et al. (1988) recommend a systematic organizational assessment and describe procedures that include surveys, observations, review of records, interviews, and analyses of various elements of the system. This recommendation reflects their process, or systems, perspective. The material on potential disincentives presented earlier in this chapter also provides information relevant to understanding factors influencing the decision-making process.

If the process of problem clarification and analysis yields sufficient consensus to proceed, it will also provide a basis for clarifying program goals and tailoring them to identified needs. Alternative options for structuring intervention assistance programs are then evaluated in terms of the organization's needs and resources. A frequent recommendation in the literature is to start with a small program or pilot project.

Mobilizing resources and gaining commitment. Substantial administrative support is repeatedly described as necessary for program success. It needs to be mobilized rather early in the decision-making process. The importance of obtaining the sanction and support of *all* relevant stakeholders is stressed by Rosenfield (1992) and Zins et al. (1988). Included among the stakeholders they mention are teachers, the teachers' union, building and district administrators, special services staff, and parents. Organizational analysis may reveal others as well. Support may be obtained by involving representative groups in problem analysis and planning. All should be kept informed of program status and have an opportunity to provide input. Mobilizing resources also involves finding ways to fund the program.

The operating plan. Careful team planning goes into producing an operating plan for implementing the program. The team who works on this has to prepare a working document and addresses a multitude of practical issues. This working document should include

1. Program purpose.

2. Specific goals, clearly defined so they can be evaluated.

3. Program description.

4. Recipients of the services.

5. Program cost and ways resources will be provided, including funding.

6. Operational procedures for providing intervention assistance to individuals and for coordinating the service delivery program (e.g., what actually will be done and who will do it, staff roles, leadership, meeting times, record keeping).

7. Plan for sharing information about the program with identified stakeholders.

8. Plan for staff development and training in consultation and teaming strategies.

9. Plan for ongoing program evaluation (integrity of model implementation as well as outcome data).

10. Time table for the various tasks that have to be accomplished.

Program Implementation

During this second stage, the program is actually put into practice. Intervention assistance is provided, training now moves to skill development, support structures for addressing faculty concerns are put in place, and evidence is gathered to evaluate program effectiveness. The effectiveness of the structures put in place and refined during this stage impacts strongly on whether the program eventually reaches the third stage of change, institutionalization, to become part of the structure and fabric of the school (Rosenfield, 1992).

The multidisciplinary team model. Many intervention assistance programs have adopted a model in which multidisciplinary teams are used for consultation and problem solving. The rationale for their use is that they increase the breadth of knowledge and skills available for problem solving and, further, that they serve as models for collaborative professional functioning. Rosenfield (1992) suggests that their popularity may be enhanced by their similarity to the structure common in schools under current special education law. These teams may include an administrator, special services personnel (e.g., psychologist, guidance counselor, nurse, social worker, speech and language specialist), a special education consultant or teacher, and a regular education teacher, all of whom receive training in consultation and team strategies. Zins et al. (1988) recommend that such teams be standing, rather than ad hoc, teams and that the number convened for any group decision making be seven or fewer.

Some ingenuity is needed to fix upon the time that a team can meet because of the number of people involved. Once found, it seems preferable to make this a standing, weekly time so that it becomes an integral part of school functioning. Zins et al. (1988) suggest 60 minutes weekly to allow the team to meet with two teachers or hold in-depth discussions. Chalfant and Pysh (1989) warn that care must be taken to establish efficient procedures lest meetings be perceived as burdensome and wasteful. They recommend clearly identified agendas and verbal economy practiced by team members.

In general, multidisciplinary teams reserve group problem solving for the most complex cases or circumstances when communication among a number of people needs to be facilitated. Intervention assistance is primarily provided by individual consultants. While this reflects a parsimonious use of resources, the balance between individual consultation and team problem solving also may be influenced by team composition — specifically, whether or not an administrator is a team member. Zins et al. (1988, p. 179) seem to be alluding to this when they comment that individual sessions for problem solving may minimize difficulties stemming from the reluctance of school personnel to discuss problems when the principal is present. Descriptions in the literature (e.g., Chalfant & Pysh, 1989) suggest that group problem solving may be a more typical service delivery system when teams are composed entirely of teachers. Currently no data exist to evaluate whether one or the other model is more effective or whether administrative participation is best sought in team membership or leadership.

Someone has to have responsibility for directing the team and facilitating the problem-solving process during meetings. Responsibility also has to be assigned to someone to "organize team meetings, receive referrals, and monitor the status of all cases" (Rosenfield, 1992, p. 36). The selection of a "systems manager" to perform this function was identified as a critical dimension of Instructional Consultation teams. The various leadership responsibilities may or may not be assigned to the same individual.

Intervention assistance process. Graden, Casey, and Christenson (1985) provide the following (multidisciplinary team) model for stages of the prereferral intervention process:

- *Stage 1: Request for consultation.* The classroom teacher requests consultation. This can be an informal process in which the teacher requests problem-solving assistance from a building consultant or a formal process in which all initial referrals are screened by a building team and then assigned to a consultant.
- *Stage 2: Consultation.* Collaborative consultation takes place to (a) identify problems in behavioral, measurable terms; (b) set priorities for action; (c) analyze relevant variables, including classroom variables; (d) collaboratively design an intervention; (e) implement the intervention; (f) evaluate the intervention; and (g) provide follow-up. Intervention plans may include the student, parents, or other school personnel.
- *Stage 3: Observation.* If the intervention plan is not successful, the consultant collects additional data through detailed observation of the student and the instructional/teaching environment. Based on this data, further interventions are planned collaboratively by consultant and teacher, and a meeting is held with the student and/or parent to discuss instructional/behavioral changes. Interventions are implemented and evaluated. If successful, the process ends with provision for follow-up.

Gresham (1989) recommends that this stage of observation also include monitoring whether the treatment is being implemented as planned and describes procedures for doing so. One of these procedures involves rating each component of an intervention for its occurrence/nonoccurrence and computing percent integrity. Fuchs et al. (1990) provide evidence that oversight (e.g., explicit written instructions and monitoring) may be needed to insure fidelity of implementation.

- *Stage 4: Conference.* The consultant and teacher meet with the team to decide whether to continue with the intervention, try another one, or refer the child for psychoeducational assessment and consideration of special education eligibility. (Although parent participation is recommended, a large team can be overwhelming; other ways of involving parents may be more appropriate in many circumstances.)
- *Stage 5: Formal referral.* If appropriate, the student is formally referred for evaluation and enters the child study process with due process regulations. This evaluation should use data collected from Stages 1–4.
- *Stage 6: Formal program meeting.* The formal review meeting, traditionally used in school programs, is held to determine eligibility and the extent of special education services. If mandated, the instructionally relevant data that has already been obtained through trying different interventions is used to develop the Individualized Education Plan (IEP).

Maintaining records of the process. Records of the intervention assistance process need to be maintained. Such records provide accountability data (documenting the amount and nature of services being provided) in addition to data needed to monitor individual case status. Well developed forms also help guide the process by specifying information needed to assess problems and successive stages of contact. Those developed by Fuchs and Fuchs (1989, p. 280), for example, include written "scripts" to orchestrate the stages of behavioral consultation. Forms compatible with the process described by Graden and her colleagues can be found in Salvia and Ysseldyke (1991, chap. 25).

Evaluation

Evaluation should be an essential, ongoing component of all aspects of intervention assistance programs. Data needs to be collected to evaluate (a) implementation, that is, whether the program is being implemented as intended; (b) the effectiveness of individual interventions; and (c) program outcomes. Examples of the kind of data that might be collected for each of these respective categories are:

1. Implementation: checklists to see whether critical dimensions of the program are in place, interviews with team members and teachers, reviews of records, analysis of tapes of the consultation process.

2. Effectiveness: frequency of target behavior, teacher ratings, single-subject and multiple-baseline designs, teacher satisfaction with intervention results.

3. Program Outcomes: referral and placement patterns, number of requests for consultation, changes in teachers' attitudes, changes in teachers' classroom management skills, consumer satisfaction, outcome of individual interventions, student academic achievement.

One can easily see that it is a major undertaking to plan evaluation procedures. It is no less an undertaking to collect data and analyze it so that it provides useful information about what works well and what should be changed. Effective efforts to evaluate programs (as well as individual interventions) require collaboration between program participants; it is important that participants perceive the evaluation system as responsive to their needs and to their suggestions for changes.

SUMMARY

The emergence of intervention assistance programs presents psychologists with exciting opportunities to use consultation as a framework for delivering services and to focus more of their efforts on resolving student problems within regular classrooms. The programs are support systems intended to assist teachers in generating and implementing intervention strategies *prior* to seeking referral for consideration of a more restrictive program. As such, they represent the most concerted and organized effort to date to correct a number of problems associated with service delivery under PL 94-142. They come in for their share of controversy, however, because they may be seen as "a vehicle for or obstacle to special education" (Zins et al., 1988, p. 63). State education agencies, for example, have seized upon the programs as a strategy for containing spiraling special education placements and costs. Friend (1988) also cautions:

> The impact of the REI on consultation may thus eventually be either positive or negative. It will be positive if it results in the clarification and refinement of the concepts and practices of consultation. It will be negative if consultation and the Regular Education Initiative come to be perceived as synonymous. (p. 10)

Currently, the efforts of practitioners and researchers working in this area are devoted to identifying and creating the conditions necessary for successful intervention assistance programs. These conditions as well as the obstacles to creating them are given major attention in this chapter. Best practice guidelines are given both for developing a program and for providing intervention assistance in individual cases.

Best Practices in Facilitating School-Based Organizational Change and Strategic Planning

Howard M. Knoff
University of South Florida

OVERVIEW

Today's children are coming to the schoolhouse door significantly at risk for both educational and social failure. According to the Children's Defense Fund (1990), "the mounting crisis of our children and families is a rebuke of everything America professes to be. It also will bring America to its economic knees and increase violence and discord within this country unless we confront it" (p. 3). As examples of the broad-based problems currently facing our children and families, this report highlights the devastating statistics regarding school dropouts, child runaways, abuse and neglect, teenage parents, drug and alcohol abuse, children killed by guns, and the effects of poverty and homelessness on America's children (p. 3–5). On a positive note, the decade of the 1990s may turn out to be one of the most important relative to rededicating ourselves to the educational and social needs of children and youth in America, but only if our nation's schools are prepared to respond to the challenges described above. Significantly, when the divorce rate, the number of two-parent working families, and our nation's health care crisis are factored in, virtually every student in this country is potentially at risk.

Starting with the 1982 National Academy of Sciences report (Heller, Holtzman, & Messick, 1982) addressing the fundamental problems that exist in the provision of services to handicapped and at-risk students, continuing with the 1983 *Nation at Risk* report of the National Commission on Excellence in Education, and finishing with the National Governors' Association educational summit in the Fall of 1989 to specify the nation's educational goals for the coming 10 years, the commitment to educational reform has been sounded at national, state, and local levels. With our National Education Goals and the Goals 2000 legislation now in place, all of our schools have benchmarks recognizing the importance of children's academic, social, and learning readiness skills to their educational success. The question that now remains is, Do our individual schools have the skills, resources, motivation, and wherewithal to plan for and actually effect organizational change such that these goals can be attained? This is the focus of this chapter, a chapter whose primary assumption is that school psychologists need to be primary players *and facilitators*, at the school level, in organizational change, strategic planning, and school reform.

Introductory Assumptions

Prior to a discussion of how to facilitate organizational change and strategic planning, a number of assumptions must be reviewed and accepted as follows:

1. Organizational change and strategic planning are natural, necessary, and ongoing processes in any healthy organization.

2. Organizational change and strategic planning initially involve a number of people working together as representatives of the larger organization. Eventually, all members of the organization work together in a dynamic partnership with defined goals, roles, and activities to bring about change.

3. Even with this representative group working together, organizational change and strategic planning generally involve one or two individuals who oversee, guide, and facilitate the process.

4. In the schools, some seemingly child-focused problems are actually building, systems, or community problems that must be addressed at multiple levels using a problem-solving process that results in systematic, multifaceted intervention and substantive change.

5. The facilitator of organizational change and strategic planning need only be skilled in overseeing the process — no specific school-based profession has primary ownership of this facilitator role.

Unfortunately, until recently individual schools have rarely engaged in systematic organizational development and strategic planning processes. Thus they have not recognized that these activities are natural, necessary, and ongoing processes in any healthy organization, nor have they learned how to carry them out efficiently and effectively. Significantly, the vast majority of the early initiatives resulting from the *A Nation At Risk* report, from 1983 to approximately 1990, were federal- or state-imposed legislative or administrative top-down mandates that increased the oversight, standards, and accountability of schools, teachers, and students, but did not provide a blueprint for successful programs and interventions — or funds, for that matter — to attain this accountability (Bacharach, 1990; Sergiovanni & Moore, 1989).

From 1990 to the present, however, the school reform movement has recognized that substantive change will come only with school-level change, and thus, the focus has shifted to encouraging (or mandating) schools to organize comprehensive, bottom-up grass-roots initiatives that involve parents, community leaders, and school personnel as equal and responsible partners. Yet at this level numerous hurdles — such as financing, time availability, and needed staff training and supervision — exist that potentially will limit and frustrate the school reform process. Indeed, a recent publication by Seymour Sarason, *The Predictable Failure of Educational Reform* (1990), highlights a number of additional reasons why school-based reform may never reach expected levels and what we can do to avoid continued failure. Specifically, Sarason expects today's school reform process to fail for the following reasons:

1. Many of the people writing school reform reports and passing legislation have never worked in school systems, do not understand school systems, and have no idea what will work and what will fail.

2. School and communities do not understand how unique the United States is in its racial, ethnic, and cultural composition, and how we will need to adapt to the social and academic realities of this composition both as adults working together and as adults working to help children.

3. The individuals "facilitating" the reform process do not understand their schools or the reform process in the context of either their schools' history or larger social systems. They are looking for the causes and solutions of system problems rather than for the resources needed to reconceptualize and redesign new systems. Further, they want guarantees ahead of time that change will work.

4. School leaders do not understand that schools exist to facilitate on an equal basis the development and growth of both students and educational personnel.

5. School leaders really do not understand that this process requires changes in thinking and behavior. They do not know how to effect these changes, and they do not recognize the difference between power and influence.

6. School personnel do not want to confront and change the existing power relationships among administration, teachers, other staff, and parents such that true collaboration and shared decision making can exist.

7. School leaders do not understand that, left unchecked, schools will respond to reform in ways that minimize the effort needed and the degree of real change required. This avoidance response, however, is directly correlated with the degree of powerlessness felt by those most responsible for the change.

School reform means change. And without a guided organizational change and strategic planning process that involves parents, community leaders, *and* school personnel, building-based change will be extremely difficult to accomplish. As a first step in this process, all of the participating parties need to learn how to collaborate and strategically plan for school-based reform. This learning may take from 3 to 5 years, it may require an outside consultant or a full-time staff facilitator, and it may be made even more difficult if the school is required, as many are, to implement the change process at the same time that the school-based management or advisory team is learning it. But it must be done, it must be focused on increasing students' social and academic learning and development, and school psychologists must be involved — potentially as the primary facilitators of the process. By way of summary, Goodlad (Quinby, 1985) concludes:

> Cosmetic changes can be legislated and mandated; the ways children and youth acquire knowledge and ways of knowing cannot. These depend on the knowledge and creativity of teachers. Better preparation of principals and teachers along with help and time for designing programs *at the site*, are necessary ingredients of school improvement. This message is at best only at the rhetorical level of acceptance at policy makers seeking to improve schooling. Unless it becomes a guiding principle of action as well as faith, little more than peripheral changes in the central curricular and instructional functioning of schools is likely to occur. (p. 19)

BASIC CONSIDERATIONS

In order to coordinate and facilitate a school-based organizational change and strategic planning process, school psychologists must understand and have expertise in three primary areas: (a) the problem-solving and planning cycles of a school from an organizational perspective, (b) the characteristics of an operating school district from a systemic perspective, and (c) the steps in a strategic planning process. Each of these will be discussed in detail below.

Planning and Problem-Solving from a District Perspective

Problem solving is needed and occurs in virtually every area of our personal and professional lives. Similarly, problem solving is used in virtually every area of business, politics, education, human services, and civic planning. Although some use more or fewer stages, problem solving typically is divided into four sequential stages: problem identification, problem analysis, intervention, and evaluation.

1. The problem identification stage involves actions that help (a) to operationally define the referred problem, whether it is of an individual nature or an organizational nature; (b) to specify the goals of the consultation, problem-solving, and/or planning process; and (c) to begin to verify the existence and extent of the problem and to generate hypotheses to explain why the problem is occurring.

2. The problem analysis stage involves actions whereby (a) the referred and operationalized problem is fully investigated in all of its ecological, organizational, situational, and behavioral contexts; (b) the hypotheses generated to explain the problem are assessed and confirmed or rejected; and (c) interventions related to the confirmed hypotheses are identified and developed while their potential acceptability, social validity, treatment integrity, and generalizability are concurrently evaluated.

3. The intervention stage involves (a) the development of the organization and its members' capacity to implement the intervention plan; (b) the identification of criteria to determine whether the intervention has been successful or not, the methods to evaluate this success, and an estimate of the amount of time needed to begin to see this success; (c) the actual implementation of the intervention plan; and (d) a determination of whether revisions or adaptations of the intervention are necessary to increase its effectiveness or to respond to unexpected outcomes.

4. Finally, the evaluation stage determines (a) formatively and summatively whether the goals of the problem-solving process and the intervention have been met; (b) how the intervention's implementation process was qualitatively perceived; (c) how long the intervention plan should be continued and if it needs to be changed, faded out, or discontinued as a function of continuing success; and (d) the degree to which the organization and its members can independently continue the intervention and whether ongoing consultation and problem solving are needed.

Significantly, individual schools attempting school reform must recognize that different parts of the school system use the same problem-solving process, yet they use this process in different time cycles (see Figure 1). This not only makes school-based reform a more complex process, especially if the school district is larger and more bureaucratic, but it reinforces the need for strategic planning. As an example, most schools do their budgeting and grade-level planning in 1-year, action-planning cycles. Often this planning begins by January or February at the latest and is completed no later than March, when the school must submit its budget to an assistant or area superintendent or to a business manager. From a school reform perspective, it is important to recognize the symbiotic relationship between school improvement goals and the budgeting process. While the ideal situation would be to have the goals determine how much of the total budget is dedicated to instruction and student progress, reality dictates that a lower than desired percentage of a school's budget will go to school reform and that schools must prioritize their goals according to the limited dollars provided. Another reality that must be integrated into the school reform process is that individual schools typically budget themselves on an annual basis. While businesses can set 5-year goals and budget accordingly, the annual nature of each school's budget and the lack of carryover funds make long-term goal setting and attainment very difficult.

Within a school, most grade-level teams (e.g., in an elementary school) or departments (e.g., in a high school) can respond to specific problems within 1 or 2 months (so long as they don't involve major financial expenditures), and they can determine the success of their problem solving often within 3 to 5 months. Moreover, most *teachers* in a classroom can respond to a situation, through effective problem solving, in a matter of 1 or 2 weeks, and then see the impact of their efforts within a month's time. The point here is that the closer one gets to the classroom level, the faster the problem-solving or action-planning cycle can occur. At a building level, problems are typically more complex: they often have budget, scheduling, or personnel implications, and thus the problem solving often requires many months and sometimes can only be addressed across school years.

At a district level, problem solving and action planning typically occur in 3- to 7-year cycles. Essentially, this means that school-based problems that require district-level change have to wait until the planning, budgeting, and implementation cycle phases in, and that some problems may be addressed by the district only if they occur across a significant number of schools. As an example, a school may find that the newly adopted reading series is not sensitive to the background and culture of its lower SES and at-risk students. Since most districts purchase their basic academic textbook series (e.g., in reading, math, and spelling) in at least 7-year cycles, this problem is likely to exist until the next series is adopted, unless the school chooses to expend a great deal of time and money to review and buy a new series. Even from a policy level, most school districts take from 2 to 4 years to implement any new policy if it involves acceptance, dissemination, training, and execution.

For a summary of this section, please refer to Figure 1, which diagrammatically shows the problem-solving process across the multiple time cycles that exist within a school district. From an organizational perspective, the strategic sequencing and integration of these cycles are critical, as is the district's capacity to streamline some of these cycles at times, while recognizing that not all change can occur immediately. Finally, the importance of the evaluation stage must be emphasized once again. If the desired outcomes of problem solving are not occurring, all four stages must be reviewed. More specifically, the wrong problem may have been identified or it may have been analyzed incorrectly, the wrong interventions may have been chosen or they may have been implemented without treatment integrity, or the evaluation methods themselves may be providing false negative readings when acceptable results actually have occurred.

Characteristics of an Operating School District

In order to facilitate organizational change and do strategic planing, school psychologists must understand the characteristics and interdependencies within an operating school district. With this understanding and an understanding of the developmental and critical events history of the school district, certain processes (such as specific power relationships, how decisions are made and by whom, and how particular people were appointed to their current positions) become more comprehensible, and others that are critical to the change process become more predictable. In the end, however, organizational change is not always a systematic, cause-and-effect process. Clearly it is always easier for a strong leader to facilitate change when entering a system in crisis, or near-crisis, or a system frustrated because of chronic inertia and mismanagement. Similarly, a well-developed strategic plan can be thwarted by a crisis event (e.g., a community's rejection of a bond issue, the death of an important staff person, or a natural crisis like a hurricane or a flood), which may completely derail the process for many years.

Below, the characteristics of an operating school district will be briefly described (see Figure 2). These have been adapted from Egan (1985), and they are organized in four major systems: the receiving system, the performance system, the human resources and people system, and the pervasive system variables. In total, the school system must be viewed as an ecological system that includes the home and the community, and it must be recognized that this ecological system both creates and identifies its own problems *and* has the resources and capacity for innovations to solve these problems.

The receiving system. The receiving system is comprised of our primary clients, the schoolchildren whom we serve, and our primary goal is to create and maintain an operating system that maximizes their social and academic development and progress. Critically, however, the organizational change and strategic planning process may identify secondary goals and interventions that involve other clients, such as families and younger preschool students, and that preventively help to support our primary goals. In fact, given our current poverty rate, the number of teenage and single parents, the increasing number of students who are not socially or academically prepared when they enter school, and the increasing number of full service schools, the inclusion of families and younger siblings in the school's receiving system makes eminent sense.

In analyzing the receiving system, the answers to a number of questions beyond "Who are our primary or targeted clients?" become critical. These questions include the following: What are our clients' needs? What do *they* identify as their own needs? What are their prescribed versus *felt* needs? What are their goals? How attainable do they feel that these goals are? From a strategic planning perspective, the answers to many of these questions will require both a client needs assessment and an analysis of at least the home and community environments, including their demographic histories. From an advocacy perspective, we need to make sure that we are integrating and reflecting the real needs, goals, and desires of our clients into our organizational change process, and that we are not choosing only those goals that are convenient or expedient. Significantly, advocates often are not members of the group they advocate for and thus sometimes never fully understand the group, remaining unaware of the group's subtle needs and reasons behind those needs.

The goals for this system are (a) to identify those client groups most related to the social and academic progress of the students in the school; (b) to understand the historical and environmental characteristics that impact this progress; (c) to analyze the client groups' strengths, weaknesses, resources, and limitations; and (d) to determine especially why the weaknesses exist, so that school reform goals can be targeted to them. In doing this, primary, secondary, and tertiary prevention interventions likely will emerge. Ultimately, however, the organizational change process should focus on primary and secondary interventions at system and building levels, and on providing educational personnel the skills and resources to implement the tertiary prevention interventions.

The performance system. The performance system involves the organizational and strategic planning aspects of a building's system that help it to reach its student-focused academic and social goals. Minimally, there are five elements to this system: the building's mission; the major aims or goals of the building that are consistent with and operationalized

FIGURE 1. Problem solving within school districts as correlated with time and planning cycles.

from the mission; the tasks, programs, or activities that will lead to the attainment of the aims; the materials and resources needed by the school's personnel to implement the programs or activities; and the specific outcomes that each program will accomplish, which again should cumulatively lead to the realization of the building's overall goals and the accomplishment of its mission.

A building's mission statement should identify the purpose for the organization's existence, its targeted "consumers," its desired outcomes, and how, within a particular philosophical framework, those outcomes will be attained. This mission statement should be brief, specific, and clear, but given its importance to the strategic planning process, it should not sacrifice length for its ability to communicate. Indeed, the mission statement should be the statement that all within the organization point to as their defining purpose, and it should be the crystallizing perspective that integrates the performance system with the receiving system. As such, in the strategic planning process the (re)development of the mission statement most often follows the organizational and needs assessment and situational and environmental analysis steps. Below are two examples of mission statements, one from a school district and the other from a school building. Note that the building statement is somewhat more specific and tailored to its distinct population and circumstances.

> The General County School District is dedicated to enabling students to develop their individual capabilities for a lifetime of learning and for responsible, productive participation in a diverse and changing world.
>
> The Specific Elementary School will prepare each child to meet life's challenges by providing the best possible learning environment with the most effective methods and resources to ensure that each child will develop academically, socially, and aesthetically.

Often underlying the mission statement are a number of visions, philosophies, or beliefs agreed upon by the school as essential to everyone's acceptance of the mission statement. One set of beliefs, adapted from the Council of Administrators of Special Education's 1992 report, *A Future Agenda for*

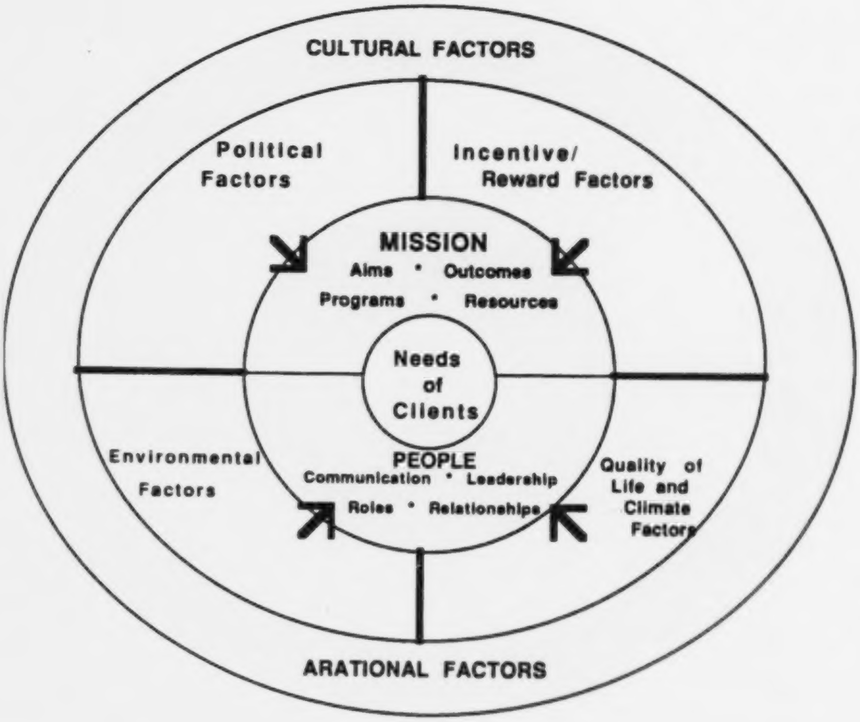
FIGURE 2. A whole-system perspective for organizational assessment, strategic planning, and systems change. From *Change Agent Skills in Helping and Human Service Settings* (p. 51) by G. Egan, 1985, Monterey, CA: Brooks/Cole. Copyright 1985 by Brooks/Cole. Adapted with permission.



Special Education: Creating a Unified Education System, is as follows:

1. Everyone is responsible for the education of all students.
2. A unified system of education integrating regular and special education must prevail.
3. Accountability for all students is guaranteed through a system of unified outcomes.
4. All educators are prepared to educate all students.
5. Funding must support a unified system.
6. Site-based management is key.
7. A unified system requires a unified, yet flexible, curriculum that is shared among and with educators and that has specified outcomes.
8. Staff development encourages problem-solving, shared resources, and continuous improvement.
9. All families feel welcome and are involved in the schooling of their child.
10. All students and staff have access to and training in appropriate technology (p 2).

Clearly the development of the mission statement and the generation of the goals that operationalize the mission statement will come more easily to the staff that embraces many or all of these details.

As noted above, once the mission statement has been developed, the building should identify the major aims, programs, needed resources, and specific outcomes that will ensure building success. Often it makes sense to develop 3- or 5-year plans, specifying the major aims and outcomes only, and then a series of 1-year plans that, if implemented, will sequentially lead to the 3- or 5-year outcomes. The generation of these plans will be discussed below in the Strategic Planning Process section. For now, it is important to emphasize the importance of identifying a priori outcomes that are relevant, observable, and measurable so that formative evaluations can be applied periodically to determine whether the programs chosen are meeting their intermediate goals or if problem solving and special intervention for these programs, due to less-than-successful outcomes, are needed.

The human resources and people system. This system involves all of the human resources within a school that are needed to implement the programs and accomplish the work that the school has identified in its strategic plan. Significantly, however, human resources also include the personnel and process management of the individuals needed, so that the whole is greater than the sum of its parts. To this end, then, schools must evaluate and coordinate their staff people, their respective roles and responsibilities, their relationships both to each other and to the school's goals and programs, and the process variables (e.g., leadership, communication, and decision-making approaches) that make it all work together. Much of this, moreover, should be driven by the specific programs identified within the performance system, so that the entire school operating system becomes more integrated and better planned.

To expand briefly, the important components of the human resources and people system are as follows:

1. The necessary people in the system are identified by the client, program, and management needs of a building. Client needs typically involve both the educational and mental health needs of the students and related family needs. These needs may necessitate both a strong cadre of primary educators and an equally strong support network of support professionals — educational specialists in particular curricular areas and health and mental health specialists like school psychologists, social workers, and nurse practitioners. While program needs may involve both educational and mental health specialists, the point here is that the programs identified in the performance system must be staffed by individuals who can best meet the specified outcomes. At times, this will require hiring staff with special backgrounds and credentials; at other times, this will necessitate training the existing staff so that the programs have the highest probability of success.

Finally, the management needs of the building are also critical to the overall success of the building. These include personnel management and supervision, office and data management, transportation and food management, and grounds and security management. Once again, personnel to address the building's management needs could overlap with those dedicated to client and program needs. The issue ultimately becomes how these individuals are organized and the degree to which they are integrated and satisfied with the level of integration required.

2. As noted above, the specification of building, program, and activity roles and responsibilities is important to determine whether the knowledge and skills needed for success exist in the building. Two points are especially important here. First, relative to the academic and social progress of students, the professional title of the individual providing a program is basically irrelevant. What is relevant is that the individual has the ability to provide the desired skills. More specifically, if a building decides that an anger control group is needed for certain students, it matters little whether it is provided by a guidance counselor, a clinical social worker, a school psychologist, or a teacher with special training so long as an appropriately trained professional fulfills the need.

The second point is that staff training should always have three outcomes: the mastery of knowledge, the translation of that knowledge into functional skill, and the attainment of a high enough level of staff confidence for both the knowledge and skill levels to be maintained over time. Unfortunately, staff training often is limited to 1-day in-services that provide some knowledge but very little skill development and/or transfer into appropriate settings. Successful staff training provides both the foundation knowledge necessary to understand the topic at hand and the skill development and supervision in the settings where the knowledge will be applied. While this may involve a significant investment in staff time, it also will reinforce the importance of the in-service area, ensure that staff have the skills needed to independently use the information with, for example, their students, and develop a high enough level of staff confidence for them to be able to apply the skills to new situations and to train new staff over the years in the lessons learned.

In the end, the specification of the functional roles and responsibilities that a school needs to accomplish its goals is critical to both the building's personnel planning and development and to staff confidence and morale. While the division of labor and tasks could result in establishing new job descriptions, the use of broad and flexible job descriptions is recommended over those that link particular professions to stereotyped and overly specific jobs and activities. Ultimately, the skills, commitment, and personal interactions of the staff will more powerfully determine the building's success than the technical adequacy of the job description.

3. The relationships and process variables part of the human resources system qualitatively involves the monitoring and reinforcement of (a) the processes that integrate the needs of the client groups, the goals of the performance system, and the personnel who will get the job done; (b) the processes that create positive school and working climates; and (c) the processes that ensure good group interactions, sound communication, strong leadership, and appropriate decision making. In essence, the school psychologist working here is functioning as a process consultant (Schein, 1969) or a human relations specialist, but clearly this is not outside of any psychologist's area of expertise. To accomplish any task, one must always attend both to process and to content and outcomes. While content and outcome often determine whether a building has the skills or capacity to complete a goal, the process typically determines whether the skills are ever applied and the degree to which they are applied. The issue here is

productivity — does a staff have the motivation and coordination to accomplish more than would be predicted by their raw skills alone, or will they accomplish only the bare minimum without regard for the loss that entails for the students?

The pervasive system variables. The pervasive system variables are building, district, and community variables that impact the performance and human resources and people systems in both positive and potentially negative ways. In essence, these are the macro-level variables that can affect system morale, motivation, and satisfaction. At the same time, many buildings are able to insulate themselves from these variables as they impact at a district level, and create their own building-level variables so that they can accomplish far more than the dysfunctional district within which they exist. In total, there are six pervasive system variables. Briefly, they are:

1. The *incentive and reward factors* are those formal and informal factors that motivate teachers and other building and district staff people to accomplish their educational goals. The most formal of these factors are the contracts that staff people are working under, and the conditions under which those contracts were negotiated and accepted. Numerous studies and public polls over the years have found that salary schedules are not the most important motivating factor keeping our teachers and other educators in the classroom and profession (usually salary ranks anywhere from 4th to 7th). However, when appropriate raises are not forthcoming, when union-administration tension over a contract exists, and when strikes or other work stoppages occur, staff motivation can decrease and the collaborative relationship between teachers and administrators (including building principals) may suffer. Overall, this can significantly interfere with the organizational change and strategic planning process, and its residual effects may persist for many years after the original contractual conflict has ended.

On an informal level, building staff are most motivated by their own collaboration and accomplishments, their feeling that they are making a difference in their students' lives, their belief that they have some autonomy in determining what and how they want to teach, the building-level recognition that they receive from their peers, and the incentives available to them — for example, opportunities to participate in advanced training, district-level leadership activities, and innovative classroom and other programs. Critically, many of these informal yet powerful incentives and rewards should be identified by and integrated into the strategic planning process. One important incentive is the incentive of time. Many organizational change programs require in-service training and high levels of cooperation, and provide this training (through the use of substitute teachers and release days) during the school day with follow-up grade-level and cross-grade-level team meetings that also meet during the school day. This provides teachers with both incentives and built-in rewards. Not only are they motivated by training that is specifically tailored to their needs, but they are rewarded when the training is successful and helps them to accomplish their goals more effectively and efficiently.

2. *Quality of life and climate factors* coexist, to a large degree, with the incentive and reward factors. Elements of these factors include those tangible and intangible needs that must be present in order to get the work of the building done (e.g., books, sufficient desks, supportive teacher-principal relationships, appropriate provisions for safety). All of these elements ultimately converge to create a positive (or negative) school climate that creates or supports the motivation and morale necessary for the incentive factors above. While there are many operational definitions of positive school climate and many, many school climate scales, a synthesis of the school climate areas most identified and used include (a) a safe and orderly environment, (b) a clear school mission with appropriate levels of planning and action and a good use of resources, (c) instructional leadership and smooth administration of the school, (d) opportunities for students to learn and stay on-task and high expectations for student social and academic achievement, (e) positive home–school relations and parent involvement, (f) student involvement and influence, (g) good teacher and staff morale, and (h) positive race relations.

3. *Environmental factors* include those community-based factors that directly or indirectly impact the management and organizational atmosphere of the school. These community-based factors include (a) the demographic and social, economic, governmental, and political status and circumstances of the neighborhood or broader community around the school and (b) issues related to population age and growth, families and households, minorities and race/ethnicity/gender status, crime, health, attitudes and values, personal income and employment, economic growth, housing, transportation, government income and expenditures, government support of the community and education, political participation, and philanthropy. In the context of strategic planning, many of these factors are evaluated in the context of an environmental scan or analysis. When doing this, the strengths, weaknesses, opportunities, and threats within the community, from the school's perspective, need to be appraised. Ultimately, the positive and negative impacts of the environment on the school must be determined and integrated into the strategic planning process. Clearly the environment potentially impacts the school's quality of life and available resources, as well as the needs of both the clients and the staff.

Mention must be made of special events and circumstances that concurrently impact a community and its schools. Unfortunately, the best examples of these events tend to be catastrophic, but clearly less intense circumstances also can be significant. As examples, one might recognize the economic, personal, and emotional impacts of such events as hurricanes Hugo and Andrew, the San Francisco/Oakland earthquakes, the Midwest floods of 1993, and other such natural disasters, and the more generic but now-too-frequent killings of and violence against schoolchildren in our classrooms and on our school grounds. These "environmental" events affect the day-to-day and year-to-year lives of our students and schools as much as the ever-present demographic and economic factors within our communities. In fact, many of these events have a more long-standing and subtle impact over time, and thus, it is important for us to strategically address and plan for them so that we can prevent their long-term effects and turn their presence into opportunities for learning and prevention.

4. *Political factors* occur both within a school district or building and outside of district or in the community. While the within-district factors are implicit in the incentive and climate factors above, the out-of-district facets are particularly pertinent here. These political factors involve ways that outside stakeholders in the system utilize their formal and informal power (in overt and covert ways) to influence the status and direction of the schools. At a macrosystem level, these political factors include local governmental (e.g., financial or morale) support, the impact of school boards and their elections, the selection or election of the superintendent, the participation of the business community indirectly or through, for example, business partnerships, and the involvement of advocacy and special interest groups. At a building level, they additionally include the involvement of the Parent Teacher Association, influential parents and community leaders, and specific client groups to the degree that they are organized or command attention.

It must be noted that while politics often is considered negative and intrusive, this does not have to be the case. In fact, through a strategic planning process, government, business, and other community leaders can be integrated into a comprehensive and integrated plan of action so that the political system can be directly used to support the broader goals of the school and school district. In the end, most communities are willing to commit time, funds, and energy to a process when clear goals are identified and important outcomes are (potentially) realized. This is the typical and expected outcome of the organizational change process, and this process often can rise above a political system bent more on power and influence than equity and excellence.

5. *Cultural factors* within a school or school system involve the stated and unstated values, beliefs, assumptions, norms, policies, and rules that affect the productivity of the school or system and its quality of life. Like any complex organization, a school goes through specific life stages that reflect its development, personnel, clients, and goals and objectives. With the introduction of a new principal, with the turnover of significant staff members, with shifts in demographics, with new mandates from state or district levels, the school adjusts, develops new norms and procedures, and redefines its culture or way of doing business. Without the understanding of a school's culture, organizational change is more difficult, random, and tenuous. With this understanding, the positive aspects of the culture can be utilized and the weaker aspects isolated, minimized, or changed.

6. The *arational factors* within a system involve those dysfunctional, skewed, and unchangeable characteristics that interfere with the system's progress if allowed. While these characteristics typically can be identified and understood, they cannot be changed — or at least their change will take a monumental effort. These characteristics include system resistance, inertia, self-interest, unpredictability, emotionality, rejection of data, hidden agendas, and many more. At the very least, arational factors must be identified so that people within the system can agree to ignore or circumvent them and not be frustrated by their presence. At the very most, arational factors might be so strong within a system that organizational change should not be attempted. Given the latter situation, one organizational option is to literally dismantle the system so that a new and improved system can replace it.

Strategic Planning Process

Strategic planning is a systematic process that increasingly is being used in education to help schools and school districts to anticipate and plan their future directions while considering both internal and community-based strengths, weaknesses, threats, and opportunities. Designed to promote and encourage teamwork, strategic planning involves a number of systematic activities that initially may take a year or more to get into place. Nonetheless, once implemented, strategic planning often takes considerably less time as it (a) develops and monitors the programs and activities designed to meet the system's mission and goals, (b) tracks their progress over time, (c) makes midcourse adjustments, and (d) attempts to anticipate other, future events that may impact the school or school district in its pursuit of educational excellence. Ultimately, strategic planning introduces a systems perspective to education that emphasizes planning, cost- and time-efficiency, and maximum resource utilization. In the long run, it can help a school or school district identify and rededicate itself to its primary mission and goals, and ensure that these goals are met effectively and efficiently.

Cook (1990) and Valentine (1993) provide two overlapping perspectives on how strategic planning should occur. Cook divides the strategic planning process into five phases: Phase I, creating a base for planning and change; Phase II, developing the strategic plan; Phase III, developing the implementation plan; Phase IV, implementing and monitoring the plan; and Phase V, renewing the plan. During Phase I, the school or district engages in the following activities:

1. An external environmental scan and analysis through which (a) economic, demographic, social, political, and education trends are analyzed; (b) national, state, regional, and local patterns in the trend areas above are evaluated; (c) scenarios that predict future environmental events and their impact on the school are created; and (d) school-based responses to the most likely scenarios, consistent with the school's resources and capabilities, are generated.

2. An internal organizational scan and analysis through which the strengths (or assets), weaknesses (or limitations), resources (or opportunities), and barriers within the school are identified, guided by the organizational map described above and depicted in Figure 2.

3. An analysis of stakeholder perceptions and expectations (as described earlier) whereby client needs and community (political) goals are identified.

4. A community education process that ties the entire process together (a) by helping the community to understand the data collected, the trends and scenarios identified, and the need for strategic planning and change; and (b) by involving the community and its stakeholders as equal partners in the remaining phases of this planning and change process.

In Phase II, the strategic plan is written by taking the results of the external and internal scans and sequentially developing a vision statement, a mission statement, strategic goals, and an outline of the implementation plan. This plan is then reviewed by members of the planning team, by critical client and stakeholder groups, and by others who might be either politically or functionally important to the implementation process. Ultimately, the feedback from this review process is synthesized and evaluated, and a revision of the strategic plan is "finalized." According to Cook (1990), the Phase II process should take approximately 3 months, and even then it is to be expected that the plan will be adapted over time.

In Phase III, the implementation plan is formalized through the development of districtwide and building-level plans. It is at this point that the coordination of the planning and budgeting time cycles shown in Figure 1 become critical. Relatedly, the implementation plan actually involves three components: a 3- to 5-year strategic operational plan, an annual operational plan, and a series of individual performance plans for each personnel unit involved in the implementation process (United Way of America, 1989). More specifically, the strategic operational plan should contain a series of operational goals and goal statements, a prioritization of these goals, the organizational unit(s) or department(s) responsible for each goal, the 3- to 5-year time frame for the completion of each goal, and the 3- to 5-year costs of the activities needed to accomplish each goal. The annual operational plan should identify, for each operational goal or subgoal, the action steps needed to accomplish the goal, the key results expected, the individuals responsible for taking the action steps, the resources and budget needed, the timelines (including beginning and end dates) required, and the evaluative process to determine the goal's attainment. Finally, an individual performance plan should involve (a) a performance planning section with areas of responsibility, operational goals, action steps to achieve the goals, and goals priorities specified; and (b) a performance review section to document actual achievements, levels of goal achievement, continuing responsibilities, and overall performance ratings.

In Phase IV, the strategic plan is implemented and monitored using the annual operational plans and the individual performance plans. As activities are completed and subgoals are accomplished, it may be necessary to adapt some timelines, budgets, responsibilities, or even some operational goals. This should be expected, and the revisions should be made with as much care paid to planning as when the original strategic plan was developed.

Finally, in Phase V, the renewal of the strategic plan is addressed. At this point, the school typically has accomplished a great deal, and yet it must determine whether its strategic direction is still valid. To do this, the school and planning team should review changes in the external and internal environmental conditions, review the mission statement and strategic goals, refocus the strategic plan as necessary, and renew the organization's commitment and energies toward the next level of accomplishment.

Valentine (1991) organizes her strategic planning process into five levels: Level 1, the preplanning stage of the planning process; Level 2, redefining the organization's direction; Level 3, developing the strategic mind-set; Level 4, implementing goals, objectives, and strategies; and Level 5, reassessing and institutionalizing the change process (see Figure 3). While Valentine's strategic planning process appears more complex and comprehensive than Cook's (1990), hers is actually just a descriptive expansion. Thus, it is instructive to review her process as shown in Figure 3 and compare it to Cook's approach above. In the end, every facet of Valentine's model has already been described. It does, however, provide a good summary to this section of the chapter.

Creating Strategic Change within the Organization

BEST PRACTICES IN THE AREA

From a strategic planning perspective, much of the discussion above has identified the critical steps and best practices in facilitating school-based organizational development and change. From a school psychological perspective, what remains is a discussion of the steps that school psychologists need to take in order to actually implement the change process. This will be discussed in five phases: Phase I, initiating the strategy; Phase II, preparing for implementation; Phase III, training for program implementation; Phase IV, implementing the planned change process; and Phase V, evaluating the planned change process.

In Phase I, the school psychologist makes an administrative entrance into the school with the express goal of facilitating the strategic planning and organizational change process. While this process often requires a series of meetings for relationship building and the clarification of change goals and objectives, it can move more quickly when the administration has a sound grasp of the organization's strengths and weaknesses and a commitment to true change. In accomplishing the tasks of this phase, the school psychologist should do the following:

1. Meet with the principal and/or the administrative team

2. Orient the administrative staff and other key personnel to the conceptual underpinnings of strategic planning and organizational change and describe its goals, strategies, and likely outcomes

3. Obtain administrative approval to proceed with the process and contractually agree on the official goals, outcomes, and timelines needed
4. Identify the key participants who, with the principal, will facilitate the planned change process
5. Begin to learn as much as possible about the organization, including its organizational structure and personnel, formal and informal rules and norms, policies and procedures, and organizational history and environment

During this phase, the school psychologist must determine (a) whether the building is ready for strategic planning, (b) whether she or he has the skills and resources to facilitate this particular change process, and (c) whether she or he wants to be the facilitator. In making these decisions and in managing the entry process embedded in Phase I, the school psychologist should do the following:

1. Assess his or her personal skills and the organization's history of change efforts before agreeing to lead the consultation process

2. Specify, at least informally, the amount of time, effort, and money that may be needed to complete different parts of the planning and change

3. Clarify potential goal differences (e.g., administrative- versus staff-driven change, crisis- versus prevention-motivated change, outcome versus process change) between the school psychologist and the administration

4. Establish a written or verbal contract with the administration, making sure that outcomes, timelines, and areas of responsibility are explicit

5. Emphasize that change is sequential and time-oriented, and that the ultimate goals are system efficacy and the ability to anticipate and prevent future problems

6. Emphasize and communicate the complexity of the consultation relationship relative to both staff and administration, discussing especially issues of dependency, authority, confidentiality, and competence

In Phase II, the school psychologist begins the preparations for implementing the planned change process by making a formal entry with the building staff. At this point, the staff complete the same groundwork done earlier with the administration, and the process from the environmental analysis and organizational assessment through the development of action plans is begun. In accomplishing the tasks of this phase, the school psychologist does the following:

1. Reenters the building at the staff level

2. Orients the staff to the concepts, goals, and strategies of the planned change process

3. Obtains staff agreement as to their participation, desires, and expected outcomes

4. Identifies formal and informal key stakeholders and organizational gatekeepers

5. Does a preliminary study of the building's organizational climate and climate change potential and its current mode of operation and functioning

6. Establishes a strategic planning team that represents a cross section of the staff to facilitate the organizational change process

7. Completes the environmental analysis, organizational assessment, and other facets of the strategic planning process

By Phase III, the annual operational plans should be complete, and the school psychologist has identified the training needed by the building in order for the strategic plan to succeed. For example, given the goal of improving the social and academic skills of students in an elementary school, the staff may identify the need for social skills training, a curriculum-based assessment process tied to curricular interventions, and a parent-involvement program. At this point the training program must be delivered so that staff have the knowledge, skill, and confidence to implement the various facets of the plan. During this process, the school psychologist also should monitor the staff's commitment and reactions to the training and the building's changing group climate. Critically, the school psychologist *should not* proceed to the actual implementation of the planned change process until all of the staff are trained in the needed skills and components.

In Phase IV, the planned change process is fully implemented, and in Phase V the process is formatively and summatively evaluated, looking at both outcome variables (e.g., increases in student achievement, decreases in student retentions and suspensions) and process variables (e.g., satisfaction with the change process, improvements in school climate). During these phases, the school psychologist should attend and respond to potential staff and administrative resistance, while ensuring that building personnel develop skills in the planned change process itself so that they are able to independently manage and renew the process over time. In the end, three questions become critical: Are we accomplishing our goals? Are we doing our job? How are we doing the job?

SUMMARY

This chapter has focused on the important steps and procedures that facilitate school-based organizational change and strategic planning. After providing a context and the assumptions reinforcing the need for such change and planning, the stages of problem solving were described, focusing on both the individual school and the school district. The importance of coordinating the change process with a district's various planning and budgeting cycles was emphasized, and the characteristics of an operating school district were described by analyzing the receiving system, the performance system, the human resources and people system, and the pervasive system variables. Two perspectives of strategic planning were introduced with five phases being typical: Phase I, creating a base for planning and change; Phase II, developing the strategic plan; Phase III, developing the implementation plan; Phase IV, implementing and monitoring the plan; and Phase V, renewing the plan. The chapter concluded with a discussion of the steps that school psychologists need to consider as they implement organizational change and strategic planning at the building level.

Throughout this chapter, it has been assumed that school psychologists can and should be primary facilitators in the organizational change and strategic planning process. As noted in the introduction, today's children are coming to the schoolhouse door significantly at risk for both educational and social failure. School psychologists are the best trained mental health and educational specialists in the schools today. We must take the responsibility for guiding our schools through the reform process begun in 1983. We must make sure that the next generation of schoolchildren is prepared to succeed — not only at the schoolhouse door, but when passing through that door and entering the workforce and our communities.

hensive picture and analysis of the functioning parts of the school, school district, and school culture. In order, Egan describes the performance system, the people, and the pervasive variables that impact the school, along with ways to assess the school and community environments, to manage school personnel for success, and to create the reward and incentive systems that help schools to work.

Sarason, S. B. (1990). *The predictable failure of educational reform: Can we change before it's too late?* San Francisco: Jossey-Bass.
Sarason, in his inimitable style, analyzes the American school system and its culture to determine whether the school reform process has any hope of success. Based on his experiences and interactions in the schools and with his typical incisive and no-holds-barred style, Sarason identifies the many pitfalls at the school level that, if left unattended, predict the failure of the current reform process. He maintains that educators do not understand the reform process, they are not willing to change the entire system, they do not want to deal with the issue of power between teachers and administrators, and they do not recognize that, unless pushed, individuals will do the least amount of reforming to get by.

Valentine, E. P. (1991). *Strategic management in education: A focus on strategic planning.* Boston: Allyn & Bacon.
This "book" (which is actually sold in a three-ring binder) provides a comprehensive strategic management model that is designed to assist the reader in guiding a school district through the strategic planning process. Supported by case studies and citations from the management literature, the book has three parts: Strategic Management – Its Role in Education, Planning for Strategic Change, and Creating Strategic Change Within the Organization. In addition, the book has over 30 step-by-step worksheets that operationalize the process and make the author's approach an easy one for anyone who understands the interdependent components of the school system to implement. This is a useful book that can help a reader to more completely understand the inner workings of strategic planning.

United Way of America. (1989). *Strategic management and the United Way.* Alexandria, VA: Author.
If you ever wondered why the United Way is so successful, this will answer your question. In this systematic eight-booklet set, the United Way describes in detail how to apply strategic management to communitywide planning and nonprofit administration. The booklets divide strategic planning into a six-step process that includes environmental analysis, organizational assessment, strategic direction setting, the formation of strategic plans, implementation, and performance evaluation. Supplemented by the introductory and the final "putting it all together" booklets, the set provides the reader with a comprehensive and practical resource that provides important insight and sequential procedures to the design and implementation of organizational analysis, strategic positioning, and change.

Best Practices in Supporting Home–School Collaboration

Sandra L. Christenson

>
> Theodora Ooms
> p. i, *The Family-School Partnership: A Critical Component of School Reform*

Developing partnerships between home and school to enhance the competence of children and youth takes a concerted effort. Positive family-school connections are not automatic; however, they are essential to children's optimal success in school and must become a major focus within educational restructuring efforts. There are new directions in parent involvement, which often require schools to change their practices. The quotes by Rich (1987a) and Kagan (1984) illustrate the current rhetoric about family-school relationships, that is, the need for mutual support and collaborative problem solving to address educational and developmental concerns for children and youth. Oom's quite (cited in Ooms & Hara, 1991), suggests that educators' perceptions of family power may be challenged by these new directions. To help meet these challenges, this chapter provides (a) a definition and rationale for home-school collaboration; (b) barriers to home-school collaboration and challenges for parents and educators, which are framed as essential partnership principles; and (c) *content* knowledge, such as guidelines for supporting home-school collaboration and examples of home-school collaboration strategies and *process* or "how-to" knowledge for developing home-school partnerships. The literature on home-school partnerships has expanded tenfold in the last 5 years; therefore, information in this chapter must be considered a summary, and the reader is encouraged to consult the resources listed in the annotated bibliography.

OVERVIEW

Home-school collaboration is an attitude, not simply an activity. It occurs when parents and educators share common goals, are seen as equals, and both contribute to the process. It is sustained with a "want-to" motivation from all individuals rather than an "ought-to" or "obliged-to" orientation (Christenson, Rounds, & Franklin, 1992). Hence, home-school collaboration is not (a) parents only in schools as volunteers, who are directed by the school's agenda; (b) parents serving on advisory councils and educators not listening to their needs or concerns; (c) parent-teacher conferences that are a one-way exchange of information; (d) school-to-home contacts only when a student is failing or no home-to-school contact when the parent is concerned; (e) co-location of services with no collaboration; or (f) parent education programs determined by educators to be important for parents (Collins, Moles, & Cross, 1982). Nor is home-school collaboration the one-way delivery of services to parents. Rather, home-school collabora-

BEST COPY AVAILABLE

tion or meaningful parent participation in education is the establishment of a mutual goal or shared agenda between educators and parents to improve educational outcomes for students. Ideally, home-school collaboration assumes parents and educators act as advocates and decision makers in the schools and that parents are key resources to improve their own children's education and the schooling of all children (Fruchter, Galletta, & White, 1992).

Home-school collaboration requires recognition by all involved that educational outcomes are influenced by events in the home, by events in school, and by the continuity between home and school environments (Hansen, 1986). Thus, the child's opportunity to learn includes what goes on in home and school, and the goal of home-school collaboration is to create an ethos for learning across these environments. Peter Usdan, President of the Educational Development Institute, has provided the most focused rationale for educators to create home-school partnerships for student productivity in school. At the 1989 Presidential Summit, Usdan reported that 91% of children's time from birth to age 18 is spent outside of school (cited in Ooms & Hara, 1991). In addition, educators know that there is "no pure" family or school time; a reciprocal, mutually influencing quality exists between children's home and school experiences.

The empirical basis for developing home-school partnerships to enhance student learning is strong (Christenson et al., 1992). First, benefits for all key stakeholders — students, teachers, parents, and schools — have been described in numerous integrative literature reviews; however, student outcomes are the primary reason for parents and educators to form a partnership. The literature supports the correlation between parent involvement and the following student outcomes: improvement in grades, test scores, attitudes, self-concept, and behavior; increased completion of assigned homework; higher rates of academic engagement and attendance; and a reduction in suspension rates (Henderson, 1989). Home support for learning — or what Walberg (1984) has labeled the curriculum of the home — "predicts academic learning twice as well as the socioeconomic status of families" (p. 400). The curriculum of the home includes informed parent-child conversations about everyday events, encouragement and discussion of leisure reading, monitoring and joint analysis of television viewing, expression of affection, interest in children's academic and personal growth, delay of immediate gratifications to accomplish long-term goals, realistic expectations and use of effort attributions, and structuring learning opportunities at home. Sloane (1991) succinctly described the conclusion by researchers about the effect of parent involvement on children's educational performance when she stated: "It is now well accepted that the home plays an important role in children's learning and achievement. *Some* [italics added] children learn values, attitudes, skills, and behaviors in the home that prepare them well for the tasks of school" (p. 145).

The issue of equity is apparent. We know that home-based learning programs have been successful in improving the educational status of children across different grade and income levels (Graue, Weinstein, & Walberg, 1983). Furthermore, the benefits of home support for learning are evident for a large nationally representative sample of students who participated in the National Educational Longitudinal Study. In their analysis of that study's data, Keith et al. (1993) found that parent involvement correlated with eighth graders' success in all academic areas, in part due to the increased homework completed by students whose parents were involved in their schooling. Because much of the literature is correlational in nature, it is important to remember that families are potential facilitators, not determinants, of their children's success. Nor does parent involvement in education entail shifting educational responsibilities from the school to the home. Rather, schools are more successful when they involve the home and also teach effectively. Seeley (1985) ably describes this concept of partnership as a common effort toward a common goal and contends that the product of education is not produced by schools — but by students with the support of parents, teachers, peers, and community professionals. How then can school psychologists work with families as partners to enhance students' active engagement and productivity in schools? A primary theme of this chapter is that the elements of collaboration and a problem-solving approach between parents and educators are essential.

BASIC CONSIDERATIONS

Researches have shown that today's most effective schools are those that emphasize a respect for family diversity and a desire to connect with *all* families for greater student success (Swap, 1992). Parents and educators are just beginning to learn about essential partnership characteristics. School psychologists who facilitate home-school collaboration need knowledge about the functioning of systems, family-school partnership principles, and home-school collaboration strategies as well as the ability to facilitate problem solving. Respect for family diversity and a belief that parents are partners in — not problems for — intervention are essential. In this section, four broad features of the field, barriers for parents and educators, and home-school partnership principles are described.

Features

Four features characterize home-school collaboration:

1. Home and school are two microsystems that are used to operating autonomously. This, in part, explains the blaming that occurs between the two systems when a child is having difficulty in school. It is much easier to point "the finger of blame" at the other microsystem when one knows only about the child's behavior in his or her own microsystem. Plus, one does not need to live with the consequences of the recommendations made for the other microsystem.

2. Home-school collaboration is not restricted to a specific area. Rather, home-school collaboration can be used to address a child-specific academic, behavioral, or social concern, as well as systems-level concerns such as homework, discipline, and school violence.

3. Home-school collaboration is considered primarily a preventive activity. Although the best practices articulated in this chapter are applicable to conflicting situations between home and school, the focus of home-school collaboration is ongoing dialogue and support between parents and educators to increase student success and, therefore, prevent conflict and alienation.

4. Home-school collaboration is not synonymous with parent-teacher relationships. Clearly the parent-teacher relationship is critical to student success and an important part of home-school collaboration. However, home is conceived of broadly and refers to the primary caregiver or the school contact individual in a student's home, which may be a parent, grandparent, older sibling, or neighbor. Similarly, school refers to educators, such as teachers, principals, and support personnel, all of whom contribute to the success of students.

Barriers

A basic consideration in supporting home-school collaboration is to identify barriers for parents and educators. Liontos (1992) has identified several barriers for parents and educators. Barriers for parents include feelings of inadequacy; previous bad experiences with schools; suspicion about treatment from institutions; limited knowledge about school policies, procedures, or ways to assist with schoolwork; and economic (e.g., transportation, daycare) and emotional (e.g., daily survival) constraints. Barriers for educators include inadequate commitment to parent involvement; dwelling on family problems (e.g., "These parents have too many problems of their own to get involved"); crisis-oriented or negative communication with parents; stereotyping parents as uneducated or dysfunctional; and lack of training in ways to work with families as partners. It is also important to consider other barriers for the partnership, such as limited time for communication; frequency of ritualized contact (e.g., parent-teacher conferences, back-to-school nights); differences in parent-professional perceptions; lack of funding; and lack of clarity about parents' and educators' roles and responsibilities (Leitch & Tangri, 1988; Mendoza & Cegelka, cited by Chrispeels, 1987; Swap, 1993).

Educators' practices for involving parents are crucial. Educators can invite parents into the school or reach out to parents by going to their home or community. Too often, educators will want parents to come to them, rather than going to the parents (Davies, 1991). According to Epstein (1992), if schools do not work to involve parents, then parent education and income level are important for deciding which parents become involved. If schools reach out to all parents, income level and parents' level of education decrease or disappear as important factors. Based on her research, Epstein speculates that "only a relatively small percentage of parents have personal problems so severe that they cannot work cooperatively with educators, given the proper assistance" (cited in Jennings, 1990, p. 21). To develop partnerships between parents and educators, barriers must be identified, acknowledged, understood, and systematically removed. Barriers should be reframed as challenges for parents and educators, who need time to engage in ongoing dialogue and problem solving about children's needs.

Home-School Partnership Principles

The five factors supported by the National School Public Relations Association (Ross, 1988) and found in successful parent involvement programs are climate, relevance, convenience, publicity, and commitment. In these successful programs, educators (a) welcomed all parents and, essentially, gave them the VIP treatment; (b) developed programs, such as workshops, based on parent input and need; (c) removed transportation and daycare barriers, making it more convenient for parents to be involved; (d) communicated with parents in multiple ways, such as a prearranged telephone chain, personal invitations, flyers, and newsletters; and (e) were committed to working with parents, which meant it was a priority school goal. Grassroots efforts to create partnerships consistently find relevance of the program or parent ownership to be a critical variable in parental involvement (e.g., Menning, 1993). Parents are involved because it is their program and meets their needs with their child.

The nine family-school partnership principles delineated by Ooms and Hara (1991) from the Family Impact Seminar in Washington, DC, underscore the seminal importance of commitment by educators. Each principle is illustrated with examples of school practices from the League of Schools Reaching Out Project (Davies, 1991):

1. *Every aspect of the school building and general climate is open, helpful, and friendly to parents.* Examples include use of "Parents are Welcome" signs and a parent center where parents meet and obtain information on child development, schools, and home learning support.

2. *Communications with parents — whether about school policies and programs or about their own children — are frequent, clear, and two way.* Examples include wall calendars with important school-related information and home-learning activities, teachers calling home to introduce themselves and giving parents a phone number and time when they can be reached, and Friday folders sent home weekly and returned with parental comments. Communication strategies are explained to all parents, not merely implemented.

3. *Parents are treated by teachers as collaborators in the educational process. Parents' own knowledge, expertise, and resources are valued as essential to their children's success in school.* Examples include schools developing learning contracts for students in collaboration with and signed by parents and parents monitoring homework after parent workshops on the topic have been conducted.

4. *The school recognizes its responsibility to forge a partnership with all families in the schools, not simply those most easily available.* Examples include varying times for conferences or open houses to accommodate needs of employed parents, conducting home visits and church visits in minority and immigrant communities, and providing interpreters.

5. *The school principal and other administrators actively express in words and deeds the philosophy of partnership with all families.* Examples include one in-service day per year to help educators learn to work with families as partners or provision of daycare for special events so parents can attend.

6. *The school encourages volunteer support and help from all parents by providing a wide variety of volunteer options including those that can be done from home and during nonwork hours.* For example, a school principal announces that parents are necessary for student success and that parents should provide some kind of volunteer assistance to the school. A list of 30 different options for parent choice is provided, and follow-up phone calls are made to obtain optimal parent participation.

7. *The school provides opportunities for parents to meet their needs for information, advice, and peer support.* Examples include parent support groups developed with PTA/PTO support and district funding of parent centers.

8. *Parents' views and expertise are sought in developing policies and solving school-wide problems; in some schools parents are given important decision-making responsibilities at a policy level.* Examples include a parent-educator committee to review and monitor the development of a broad-based health and sexual education program and the school-site council, as part of school-based management, to administer the school's discretionary funds.

9. *Schools recognize that they can best help parents provide a home environment conducive to children's learning if they facilitate their access to basic and supportive services.* Examples include collaboration with community agencies for before- and after-school care on site and a family services center in the school, which provides basic health screening, counseling, adult literacy and education courses, and clothing exchanges.

In closing, it should be apparent from these principles that educators need to examine their current practices with parents. *The partnership principles emphasize schools reaching out to all parents and initiating efforts at every grade level to involve parents in learning activities, school programs, and school-related decisions.* Furthermore, a no-fault model, where blame is not placed on either the home or school, is emphasized. New beliefs about parents and families are evident: All families have strengths, parents care about their children and can learn new techniques, and parents have important perspectives about their children (Liontos, 1992). By fostering collaboration — or the forming of a relationship with parents where parents and educators agree to work together and share responsibility for student outcomes — school psychologists can turn those beliefs into action.

Successful programs require an infrastructure. For home-school collaboration, this means the formal connection of schools to the rest of society — family, home, and environments outside of school in which children spend most of their time (Rich, 1988). Rich suggests ways to build this infrastructure: Launch a media campaign about parents as educators, train teachers to work with families as partners, provide ways for families to help each other (e.g., parent-support groups supervised by school psychologists), involve senior citizens and the larger community, and provide learning activities that families can use with children. Clearly, the way families and educators presently interact will need to be altered. And, because there have been few links between home and school, collaboration will not be easy. School psychologists interested in developing and supporting home-school collaboration to increase student success in school will find they need both content and process knowledge.

BEST PRACTICES

Content Knowledge: Guidelines for Supporting Home-School Collaboration

Based on intervention studies designed to develop home-school partnerships (Christenson, Thurlow, Sinclair, & Evelo, 1993; Davies, 1991), five essential guidelines for supporting home-school collaboration are evident. Although both parents' and educators' attitudes are integral to the success of the partnership, researchers have shown that the school's attitudes and practices are the stimulus for partnerships. School practices, or how schools reach out to parents, were determined by Epstein and Dauber (1991) to be more important determinants of parent participation in education than were parents' educational, socioeconomic, or ethnic backgrounds. Jean Krasnow (1990), who is associated with the League of Schools Reaching Out Project, has described how schools — more than the families — are in a position to create the conditions that erect barriers to greater parental involvement. The guidelines illustrate the importance of educators thinking of parents as partners in — not problems for — instruction and intervention.

A belief in shared responsibility. Home-school collaboration depends on a belief in shared responsibility for educational outcomes. Hulsebosch (1989) defined the characteristics of both teachers who are high involvers of parents in education and those who are low involvers. She showed that low involvers believed that home and school have separate responsibilities in the socialization of children, described the negative influence of home events on school life, and saw parent involvement activities as auxiliary to the real world of the classroom. In contrast, high involvers believed classroom activities should fit with children's homes and experiences, described parents in positive terms, and saw parents as an asset and basic element of a child's education. Both high and low involvers indicated the effort was a necessary and important part of their work, whereas low involvers implied the effort was an unnecessary add-on to the real world of teaching.

Because few schools have a policy that clarifies the essential role of families in the education of school-age children and because little consensus exists about the roles and responsibilities between parents and educators, school psychologists must determine whether educators at their school site believe in parents' meaningful participation in education. These questions need to be asked of the educators:

- How would you characterize the belief system about the relationship between parents and educators with respect to children's school performance?
- Do you believe in shared or separate responsibilities between home and school?

Should the belief in shared responsibility for educational outcomes not be present, the school psychologist may want to conduct a staff in-service on the empirical basis for parent participation (Henderson, 1989) and the curriculum of the home (Christenson, Rounds, & Gorney, 1992) as well as discuss Coleman's (1987) theory of families and schools vis-a-vis the socialization of children.

Coleman (1987) proposed that home and school provide different inputs for the socialization process of children. One class of inputs — opportunities, demands, and rewards — comes from schools. The second class of inputs — attitudes, efforts, and conception of self — comes from the social environment of the household. Educational outcomes result from the interaction of qualities that the child brings from home with qualities of the school. Schools do make a difference for children; however, they do not have an equal effect on children. According to Coleman (1987): "Schools, of whatever quality, are more effective for children from strong family backgrounds than for children from weak ones. The resources devoted by the family to the child's education interact with resources provided by the school — and there is greater variation in the former resources than the latter" (p. 35). Schools can reward, demand, and provide opportunities for children to learn; however, Coleman views families as providing the building blocks that make learning possible. Families provide the "social capital" needed by schools to optimize learners' outcomes.

Coleman argues that the social capital in homes is shrinking, in part due to the reduced availability of human capital because of single parenting and multiple demands on adult lives (e.g., two-working-parent households). Where this occurs, school achievement will not be maintained or increased without influencing home environments. According to Coleman's theory, the child's attitude toward learning is influenced predominantly by messages and experiences provided in the home setting. Therefore, educators must support and strengthen parents (parents used broadly to include adults in the home) as they assume the vital role of participant in their children's educational lives.

Finally, educators need to remember that parents do not want a hierarchical "professional-client" relationship with schools (Lindle, 1989). Parents indicated a dissatisfaction with school personnel who are "too business-like" or "patronizing," or "who talk down" to them. Parents want (a) information about their child's development and educational needs; (b) educators as partners, which means parents and educators are equals, share information about the child's performance and development, and share resources to solve concerns; (c) a support network or an opportunity to learn from and share with others; (d) training; and (e) informal contact with educators or a chance to build a trusting relationship (Peterson & Cooper, 1989).

Importance of perspective taking. The degree to which parents and educators engage in perspective taking and nonblaming influences the effectiveness of the home-school partnership. Parents and educators have multiple demands in their lives, are very busy, and often are not available to each other at a convenient time or in a convenient way (e.g., telephone). Swap (1987) has pointed out that the other's lack of availability is too often interpreted as a lack of concern for the student. In addition, typical parent-school contacts are ritualized and ineffective in achieving the goals sought in home-school collaboration: meaningful dialogue and sharing of resources to enhance student learning. Parent-educator contact at the 15-minute conference or back-to-school night does not permit the development of relationships or contribute to effective problem solving. Finally, differences in perceptions, as a function of the unique aspect of the parent or educator role interfere with communication and collaboration but are to be expected and need to be understood (Mendoza & Cegelka, cited in Chrispeels, 1987). For example, educators are expected to be fair to all children, whereas parents adopt an individualized perspective, wanting what is best for their child. Educators become "specialized experts," noting one aspect of a child's development, while parents adopt a more diffuse orientation, focusing on the child's ongoing development. Educators are expected to be effectively neutral, to be able to distance themselves from the child. The parent role is the antithesis of the educator role; emotional involvement is expected. Rather than blaming each other for their perceptions, they need to use their different perspectives to construct a more complete picture of the child's performance/behavior in both home and school contexts.

Differences in attributed patterns may account for some of the difficulty parents and educators have in dealing with school problems, delineating parent-teacher responsibilities, and arriving at mutually agreeable solutions. Guttmann (1982) found that teachers attributed causes for problem behavior to the child first, the parents second, and minimized or dismissed any reasons associated with themselves. In contrast, parents attributed responsibility almost equally to the child, teacher, and themselves. Rich (1987b) interpreted the emphasis teachers place on home life as a recognition of the significance of the home as an educational environment rather than as a deficit view of the child or blaming of the family. This is most encouraging. The key in collaboration is to shift from an emphasis on who is responsible for the problem to who is responsible for the solution. This will occur when parents and educators think about their relationship differently, when they move from the concept of relationships in terms of service delivery — of "provider" and "client," of "professionals" and "target populations" — to one of complementary efforts toward common goals. Seeley (1985) argues:

> *Partners may help one another in general or specific ways, but none is ever a client, because the relationship is mutual. Providers and clients can deal with one another at arm's length; partners share an enterprise, though their mutuality does not imply or require equality or similarity. Participants in effective partnerships may be strikingly different, each contributing to the common enterprise, particular talents, experiences, and perspectives, and sometimes having different status within the relationship and control over aspects of the work to be done.* (p. 65)

Negative stereotypes about parents are destructive. Sometimes educators have fixed ideas about what constitutes a good family and proper child rearing. Most often middle-class families' behaviors and attitudes are preferred — educators see these children as coming to school with the "right stuff." Often educators perceive parents who are low income or nonwhite as deficient (Heleen, 1989). It has been shown that working-class or poor parents want their children to be successful in school but often do not understand school procedures, expectations, and how to assist their children. Consequently, these parents wait to be guided by educators. Educators have interpreted parents' behavior from a deficit-oriented model and coined these parents as apathetic or hard to reach. These parents see the school as hard to reach.

How do you think about families? Do you call them dysfunctional, or do you understand that they are affected by adverse living conditions? Do you identify family deficits or family strengths? All families have strengths; however, families differ in their energy, time, knowledge, and skills for assisting children (Christenson et al., 1993). Similarly, it is time for parents to understand the tremendous variability in student performance and that the solution for school success does not reside in the microsystem of the classroom.

School psychologists will find reframing, developing programs to reach out to all families, and increasing communication and contact between families and educators helpful tools for addressing the need for perspective taking in the partnership. Above all, they need to work actively to stop stereotypes and negative attributions to home life. These conditions, should they exist, suggest the need for information sharing and problem solving between home and school.

The importance of shared language. The degree to which the language of schooling is shared with parents must be examined by educators. The language of schooling includes grading practices, teacher expectations, curriculum goals, and homework policies. Joyce Epstein (1992), Co-director of the Center on Families, Communities, Schools, and Children's Learning, has advocated a similar approach. She suggests that parent involvement programs must make a strong connection with schooling and with the child as a student. Results from a pilot parent-interview study sponsored by the National Association of School Psychologists indicated parents needed information on specific ways to help their children at home (how to help with homework, talk about school, monitor progress), on what is happening at school (school activities, child's progress, teacher expectations), on school policies (sex education, testing, grading, discipline), and on how to be involved at school (how to communicate with teachers and help with specific problems, Christenson & Garrettson, 1992).

Also, the means by which the language of schooling is shared with parents must be checked by educators. Exclusive use of printed materials must be abandoned or equity issues vis-a-vis educational outcomes will persist. Even if parents can read, they often do not know how to apply the information to their situation. The result is that parents may know they should do something but not know how to do it. Parents are often told what to do (e.g., help your child with homework) but not told how. Likewise, educators provide parents with grades, but little information about how grades are determined. It is time to share information about child and adolescent development, school practices, home influences on learning, and ways to promote children's progress and development with parents and educators in multiple ways: printed materials (newsletters, handouts, lending library), classes/workshops, personal contact (home visit, school consultation), technology (audio, video, cable, telephone), and parent support groups. Sharing of information begins to create an infrastructure for education.

Parents need to be socialized for their role as facilitators of their child's school performance. Ames (1993), a researcher at the University of Illinois with the Center on Families, Communities, Schools, and Children's Learning, has shown that elementary school teachers who were high users of school-to-home communications reported they more often felt they could reach difficult students and help all students make progress. The school-to-home communications included strategies and practices in three categories: information about classroom learning activities (goals, curriculum, materials), information about their child's progress (accomplishments, improvement, effort), and direction to enable parents to help their children on learning activities at home. Information was communicated through newsletters, phone calls, personal notes, and work folders. Teachers' communications influenced parents' feelings of comfort with the school which then influenced parents' involvement in their children's learning. A similar study found that middle school educators' communication influenced parents' feelings of comfort with the school which then influenced parents' involvement in their children's learning; the practices enhanced the parents' belief that they could help their children, which then influenced their involvement (Christenson et al., 1993).

The focus of partnerships. Parents and educators come together when a child becomes a student; therefore, education and development are the natural link. Rich (1987a), Director of the Home and School Institute in Washington, DC, has shown "that parent participation is most widespread and sustained when parents view their participation as directly linked to the achievement of their children" (p. 63). Numerous interventionists and researchers have found that parents are more interested and involved when they learn ways to increase their child's success in school and when contacts are personal. The focus of home-school collaboration should, therefore, be to resolve school-based concerns about the educational life of the child. Parents, teachers, and/or students can initiate communication and a problem-solving dialogue about the educational concern. Based on a systematic investigation of home-school collaboration, Christenson et al. (1993) found it helpful to (a) invite parents to help solve a teacher's educational concern for their child; (b) be tolerant of and nonjudgmental about the ways parents indicate they can help; and (c) provide information, ongoing support, and consultation to parents as they learn how to assist their child's school performance. Ongoing communication between home and school is focused on the degree to which parents and educators, as facilitators of children's performance, are achieving their mutual goal: improving the child's school performance.

Vosler-Hunter's (1989) work on the Families as Allies Project is extremely relevant. Parents of children with emotional and behavioral disorders and educators participated in a number of training activities, out of which emerged key elements of collaborative relationships: mutual respect for skills and knowledge, honest and clear communication, two-way sharing of information, mutually agreed upon goals, and shared planning and decision making. These elements were most evident when problem solving was focused on those links between parents and educators — the child and the goal of their efforts — that increased the child's competence.

Options and flexibility. Home-school collaboration works best when many ways for parents to get involved exist and flexibility is encouraged. Epstein (1992) describes six kinds of activities and illustrates that parents can be involved in their child's education at school, at home, and at home and school. Because of the multiple demands on parents' lives, home-school collaboration has been more successful by negotiating educational responsibilities with parents that can be completed at home rather than expecting parents to participate at school (see next section). Herein lies the problem: Educators still quite often want parents to come to school rather than educators going to the parents.

Best practices in home-school collaboration are based on the belief that parents and educators share a goal, information directed to attaining the goal, decision making, and accountability for outcomes. This means educators need (a) to ask parents to become involved and share in the responsibility for their children's education, and (b) to admit parental help is required to resolve some educational concerns (e.g., school violence, destructive behavior). It means that parents may need to understand why their participation is encouraged by educators but not be *told* how they must help the school; rather they should be offered several options from which to select. In short, best practices in home-school collaboration set an expectation that parents will be involved; however, shared decision making will direct how they are involved.

Five variables — a belief in shared responsibility, a high degree of perspective taking, sharing the language of schooling, establishing the mutual goal of student success in school, and options for parent participation for learning — *exemplify the attitude in which all activities must be delivered.* In the next section, home-school collaboration strategies are illustrated.

Content Knowledge: Home-School Collaboration Model and Strategies

Epstein's typology. Epstein (1992) developed a well researched model of home-school collaboration characterized by six types of activities. It is critically important for school psychologists to recognize that these six activities, if all implemented, would constitute a comprehensive home-school collaboration program. Epstein found that implementing such a program involves planning and ongoing support over a 3- to 5-year period. Careful attention must be paid to implementation at each grade level. Typically parent participation declines dramatically after their children pass through the fourth grade, despite evidence that successful parent participation at secondary levels occurs when schools reach out to parents (Collins et al., 1982). The following paragraphs begin with Epstein's definitions verbatim (1992, pp. 503–505, in italics). Then ways school psychologists could provide ongoing support for home-school collaboration through either direct or indirect services are provided.

Type 1 — Basic Obligations of Families refers to the responsibilities of families for their children's health and safety, parenting and child-rearing skills at each age level, and positive home conditions for learning at each grade level. It is critical for educators to be sensitive to families' customs and cultures and provide information with the understanding that families differ in their energy, time, knowledge, and skill level for applying the information. Indirect service activities provided by school psychologists could include: Help schools provide information on parenting skills, child development, grade-level expectations, homework policies, and ways to build positive home learning conditions through printed materials, videotapes, workshops, parent support programs, and a lending library. Help schools to create a parent/family center (Johnson, 1993). Direct service activities provided by school psychologists could include: Consult with parents about specific ways to support students' learning and behavior in school, make home visits to reinforce home-based learning programs, and conduct workshops on ways to maintain healthy child development and school success across grade levels.

Given the diversity of America's families, school psychologists should not expect families to automatically understand their basic obligations or the curriculum of the home. To establish a shared responsibility for learning outcomes for students, schools must communicate this direct message: (a) children achieve more with home support for learning; (b) home support for learning can be provided in a variety of ways, and these are some examples (e.g., the restaurant menu approach); and (c) we want to work with you to increase our communication about your child's school progress and schoolwork. Schools must allow parents to decide how they can participate — or what role they can play. Finally, educators must remember that some families need only information, and others need information and ongoing support as they learn how to assume an active role in their child's schooling. For some families it is essential to determine what resources and support the family will need to fulfill their responsibility (Christenson et al., 1993).

Type 2 — Communications from the School refers to the responsibilities of schools for communications from school to home about school programs and children's progress in forms and words all families can understand and for options for home-to-school communications. Indirect service activities provided by school psychologists could include: Help develop frequent, efficient, and varied forms of all communication that are understood by all parents (memos, good news phone calls, report cards, conferences). Develop a structure for effective parent-teacher conferences, a routine phone calling/contact system, and a structure for contacting parents at the first sign of a problem. Direct service activities provided by school psychologists could include: Meet with parents to explain school programs and children's progress. Develop unique communication strategies for non-literate parents and communicate in parents' first language. Facilitate conferences and family-school meetings to develop interventions to improve the child's school success and grades, and create cooperative relationships between parents and educators.

Maintaining effective lines of communication is the most basic element of supporting home-school partnerships. The following list, which illustrates ways schools have changed their practices, is noticeably oriented to educators emphasizing the positive:

- The welcome sign is inviting.
- Educators emphasize goals for or skills they want to teach the child rather than the problems or deficits of the child in the school context.
- Parents are invited to help solve the school-based concerns, and parental input is actively encouraged throughout the process.
- Educators do not tell parents what to do (e.g., help your child with homework) but are prepared to guide and show parents (e.g., how to structure study time at home).
- Educators communicate at the first sign of a concern. Canter and Canter (1991) provide a helpful structure for teachers to use when contacting parents at the first sign of a concern. The structure includes six steps: statement of concern described using specific, observable behaviors; steps taken by the school to solve the concern; parental input about the concern; summary of new ways to approach the concern; expression of confidence about resolving the concern if home and school work together; and establishment of a follow-up time for contact.
- Ask teachers to provide four positive contacts to parents in varied areas: curriculum, good deed, child's progress, and child's strengths. Parents are invited to visit the classroom.
- Establish an ongoing contact system for *all* families. Examples include homework hot lines; use of electronic technology, such as the TransParent School Model (Bauch, 1989); and school-to-home progress reports/newsletters that provide parents with information about the classroom activity; child's progress, and ways parents can help reinforce child's learning (Ames, 1993). Some schools have used a notebook system for all students to increase communication between school and home. Assignments and teachers' and parents' comments are recorded. The power of the notebook system is that it is used school wide.
- Provide ways for all parents to learn about school policies and teachers' expectations. Strategies include orientation nights offered at multiple times, handbooks with designated policies, personal contacts for families who do not attend, and monthly workshops to discuss the language of schooling (testing, grading practices, discipline, monitoring students' progress).
- Reach out to families who do not attend or whose children are considered potential problems. Schools can conduct home visits or make phone contacts to invite parents to participate, to determine reasons for their lack of attendance (e.g., work conflicts, transportation), and to articulate that children produce more in school when parents and educators work as a team (Together Everyone Achieves More). Canter and Canter (1991) provide a structure for teachers to use when contacting a parent whose child is considered a potential problem student. Teachers are encouraged to call after a few weeks of school and to use this structure: statement of concern (e.g., I want this to be the best year for Tom); parental input about last year; parental input about this year; explain parental support is valued and critical; and express confidence that working together will help the student.

Type 3 — Volunteers refers to those who assist teachers, administrators, and children in classrooms, parent rooms, or other areas of the school; to those who assist at home; and to those who come to school to support student performance and events. Indirect service activities provided by school psychologists could include: Organize parent volunteer program to assist teachers, administrators, and children in classrooms. Ensure that schools vary schedules so all families can participate as volunteers or audience. Direct service activities provided by school psychologists could include: Train volunteers to increase their effectiveness. Ensure that transportation and daycare are provided for families. Encourage parents to attend school performances or other events. Contact parents who do not attend scheduled conferences or need follow-up contacts. Develop a buddy system to remove the barriers of transportation or alienation for some parents.

Volunteering by parents in schools is a traditional form of parent involvement and one which schools value highly, but parents' working schedules may require educators to alter their practices slightly (e.g., create volunteer activities to be done at home). Also, it is important to differentiate volunteering from establishing a shared responsibility for children's learning. At the beginning of the school year, schools often send home a list of needed volunteer activities in the hopes of recruiting parents. This approach indicates parent involvement is desirable but does not emphasize partnership. When schools invite parents to share in the responsibility for their child's school performance by indicating that efforts from school and home toward a common goal are known to produce better outcomes for students, schools are saying parents are essential, not merely desirable, to promote student success. Therefore, when schools send home the list of volunteer activities, a simple introductory sentence emphasizing the essential roles parents play in achieving positive outcomes turns the volunteer list into an example of a partnership effort.

Type 4 — Learning Activities at Home and Connections to Curriculum refers to parent-initiated, child-initiated, or teacher-initiated ideas to monitor, discuss, or assist children at home on learning activities that are coordinated with children's class work. Indirect service activities provided by school psychologists could include: Provide inservice training to teachers on home learning activities and other ways to involve parents with children's class work. Help schools provide information on how to monitor homework, grade-level expectations, and practice and enrichment activities. Teachers Involve Parents in Schoolwork (TIPS) is a helpful resource (Epstein, Jackson, Salinas, & Associates, 1991). Direct service activities provided by school psychologists could include: Meet with groups or individual parents to share strategies to increase student success in school. Plan, coordinate, and monitor interventions implemented by parents and teachers. The positive evidence for home-based learning programs (Graue et al., 1983) is strong, and parent-educator problem-solving meetings (see next section, this chapter) often serve as an entree for additional consultation and case management by the school psychologist.

Type 5 — Decision Making, Committee, Advocacy, and Other Leadership Roles refers to parent participation in decisions in PTA/PTO, advisory councils, other committees or groups at school, or independent advocacy groups. Indirect service activities provided by school psychologists could include: Help schools create participatory roles for parents and community members in PTA/PTO, advisory councils, Chapter I, and committees. Direct service activities provided by school psychologists could include: Train parent representatives in decision-making skills, collaboration, and ways to communicate with other parents about school improvement activities. Facilitate development of basic policies on curriculum, homework, and assessment. Successful home-school collaborative efforts often use these activities. In a review of programs, Kagan (1984) noted that the realization by both parents and educators that home-school collaboration must be a goal of their efforts is another essential element for success. Schools have implemented home-school teams to plan school events, to develop policies that require home and school support for successful implementation (homework, discipline), and to resolve school-based, system-level concerns (e.g., school violence). For these teams to be successful, a problem-solving orientation is necessary.

Two examples illustrate the power of a home-school team to focus on educational concerns. Referred to as the Comer Process, The School Development Program was developed in 1968 by James Comer, a psychiatrist at Yale, in collaboration with other colleagues at Yale and educators in the New Haven Public Schools (Conner, 1980). Because of the dramatic success of this project in terms of improving academic and social outcomes for students, the program has been replicated in over 100 public schools. Critical components of the program include: School Planning and Management Team (SPMT), Mental Health Team, Parent Participation Program, and Curriculum and Development. The SPMT is comprised of two teachers, three parents, and one mental health specialist and directed by the principal to establish policy and strategic planning across the key stakeholders in the school. The team coordinates school functions and maintains the focus on partnership and problem solving. The Mental Health Team is composed of a school psychologist, a social worker, and a regular and special education teacher. This team meets to address referrals and concerns, and also provides systematic training to parents *and* teachers about ways to promote social and behavioral competence in students. The Parent Participation Program offers many family-school events, employs parents as classroom assistants, and helps establish school policy by electing three representatives to the SPMT. Finally, curriculum and child development needs are met by providing monthly seminars in ways parents and educators can emphasize the academic and social skills acquisition of students. Parents and educators engage in mutual learning experiences on this project. A true partnership means the partners listen to each other, engage in ongoing dialogue about improving student success and development, and realize that problems can be solved by working as a team.

On the Partnership for Success Program (Christenson et al., 1993), a home-school team referred to as PATHS, Parent and Teachers Heading to Success, was developed for parents and educators to share information and perspectives, engage in ongoing dialogue about ways for parents and educators to assist each other, and to maintain a shared agenda for their efforts; the success of children in school. The team has developed a parent center and techniques to increase and improve home-school communication, developed and implemented a sex education program, and discussed homework policies. After 2 years, signs of finger pointing between home and school temporarily surface when a new concern is addressed. What is encouraging is that team members realize mutual support, sharing of information, and problem solving, not blame, are the answer, and with this realization, the finger pointing ceases.

Type 6 — Collaboration and Exchange with Community Organizations refers to school actions and programs that provide or coordinate student and family access to community and support services. Also, collaboration with businesses, cultural organizations, and other groups to improve school programs for children and services for families to support their child rearing and guidance of children as students, and to improve the effectiveness of the other types of involvement are included. Indirect service activities provided by school psychologists could include: Consult with teachers and administrators about forming business partnerships and community linkages to promote student success in school and family resource centers of school-linked services to meet children's needs through health and social service agencies. For example, Education Sunday refers to workshops for parents, delivered at church, about school issues. Direct service activities provided by school psychologists could include: Develop resources and a referral network. Develop/coordinate a family resource center to provide family education, counseling, tutoring, food and clothing, or routine medical care. These services are often provided by community-based professionals in collaboration with schools.

Trust-building events. Because of barriers that may exist for parents and educators, trust-building activities may be essential before other collaborative efforts can be successful. Trust-building activities allow parents and educators to "find friendly faces in the crowd" and provide socializing experiences for parents and educators. Weiss and Edwards (1992) refer to these activities as climate-building activities. Examples of activities include: grade-level bagel breakfasts, multicultural potluck dinners, and family's evening out (movies, skating, gym night). There is no limit to the kinds of activities (except for lack of creativity!) that allow educators and parents to get to know each other on an information-sharing, non-problem-oriented basis. Many of the communication strategies qualify as trust-building activities, also.

Parent-educator problem solving. Maintaining a problem-solving, nonblaming interaction style with parents is essential. Parents and educators need to meet to share information of common concern at a system level (e.g., school violence) and on an individual level (e.g., child's academic or behavioral performance). Effective meetings are based on nonblaming interactions and a problem-solving orientation and structure (Sheridan & Kratochwill, 1992; Weiss & Edwards, 1992). The structures provided by these individuals have been used to develop a parent-educator problem-solving sequence that was implemented in elementary and middle schools to design collaborative interventions between home and school. This structure can be used to address a myriad of school-based concerns (attendance, academics, behavior), thereby moving from problem admiration to problem solution. Although the steps are clearly delineated, recognize that problem solving is a concept more than a structured sequence that must be adhered to as delineated. School psychologists may wish to make some modifications while retaining the essential characteristics of information and resource sharing to achieve a goal. The stages are:

- **Introduction Stage**

  1. *Rapport Building.* This step is critical and, in a sense, related to trust building. Know the student, know the concerns, and know several positive attributes of the student. Welcome parents to the school. Mention a positive attribute of the student.

  2. *Describe the school-based concerns.* These concerns can be teacher-, parent-, or student-initiated; however, most often they are teacher-initiated. The concern is described in specific, behavioral, observable language. This statement reflects the child's current level of performance, which is usually considered to be problematic.

     - *Reframe the problematic behavior.* Reframing is a helpful strategy for building a partnership with parents. We know that parents wait to be directed by schools and want to know how to help their child be successful in school. By reframing problematic behavior to a learning goal, the desired behavior from the child has been specified. At this point, invite parental assistance. Educators indicate they will work to teach the student (Tom) the academic, social, or behavioral skills; however, they believe Tom will learn these skills faster if the parents can join the team of educators to support Tom's learning. Parents indicate whether they want to be involved.

     - *Focus on solutions.* The facilitator of the meeting (usually the school psychologist) states that the purpose of this meeting is to come up with a doable plan of action, something all participants agree with and help to implement. The tone is "we aren't here to blame anyone or look for responsibility for the problem. Rather, we are here to determine responsibilities for solutions" to the school-based concern.

- **Identification Stage**

  1. *Identify all concerns and perceptions.* Parent, student, and teacher perceptions as they relate to the school-based concern need to be shared. There needs to be a realization that perceptions will differ or what Jim Maddock, in Family Social Science at the University of Minnesota,

refers to as "truth comes in versions." Individuals observe the student in different settings. It is possible that other concerns will surface.

2. *Identify a mutual goal for the student.* After the information-sharing session, several goals may be expressed. It is important to arrive at consensus. Which goal will both parents and educators work on? There may be goals that either partner will take sole responsibility for and merely inform the other partner.

3. *Check for understanding.* Because many issues will be discussed, it is important to recap the discussion by describing the discrepancy between problematic behavior and desired behavior for the child (i.e., learning goal). Parents' and educators' efforts now focus on ways to work together to teach the desired behavior.

- **Solution Stage**

1. *Possibilities for a solution.* Because parents generally wait to be guided by educators, they are usually relieved when educators are prepared to mention several possibilities for solution. These should include what can be done at school and home and should be presented as a restaurant-style menu. Brainstorming should be used to expand this original menu. The key is to find what parents and teachers can realistically implement.

2. *Select an idea.* It is important for parents and teachers to indicate what they want to try to resolve the concern. After their selection, the school psychologist should ask, "What resources or support would you like to have as you try this idea?" For example, the school psychologist should be prepared to offer consultation, reading materials, contact with other parents, and the like. This question is important because it normalizes the notion of parents needing help around schooling issues (e.g., structuring learning time, supporting reading at home). It is an empowering statement because the focus is on promoting opportunities for parents to recognize their strengths, set their own agendas, and make constructive changes in their lives.

- **Implementation Stage**

1. *Describe the doable plan.* It is important to recap the roles and responsibilities of teachers, parents, students, the school psychologist, and others.

2. *Implementation phase.* During this time, it is important for the school psychologist or another individual to systematically contact the parents to discuss any concerns and to provide ongoing support and consultation.

3. *Evaluate the plan.* The intervention plan is successful if the discrepancy between problematic and desired behavior is closed or if the learning goal is achieved. If the goal is not achieved, *no one is to blame.* It simply was a lousy plan, and the team needs to reconvene to modify the intervention. If the goal was achieved, find a way to celebrate!

In summary, content knowledge for developing effective home-school partnerships for learning includes partnership variables, home-school collaboration and trust-building activities, and parent-educator problem solving. Problem solving is the systematic tool to alter the interface between home and school in a way to increase connectedness and minimize distance.

Process for Developing Home-School Partnerships

Time is a factor when implementing a home-school collaboration intervention versus a home-school collaboration program. Training and leadership are required for both; however, to develop a comprehensive home-school collaboration program takes 3 to 5 years. In contrast, school psychologists working with individual parents could more quickly develop home-school collaboration interventions.

Kagan (1984) reminds us that best practices for developing programs are characterized by site-specific development and leadership. Each school must ask two questions: What forms of parent participation are desirable and feasible? and What strategies can be employed to achieve them? Other questions that schools must consider throughout the development phase appear in the literature. Examples include

- What is the school's definition of parent involvement?
- Is this the same as parents and community professionals?
- Do teachers recognize the family as a system for teaching and learning?
- What are high-priority problems in the school climate, and how can parents and educators address them?
- Has the school district made a fiscal commitment (within existing resources) to development of programs?
- Does the majority of the staff believe in the benefits of home-school collaboration?
- For which groups of parents would educators say, "You will never get them involved!"?

Best practices suggest that schools need to create a team of parents and educators who are interested in answering these questions.

Epstein (personal communication, 1991) recommends a helpful process for developing home-school partnerships. First, educators, with parental input, are encouraged to identify strong school practices that involve parents at each grade level. Second, educators are encouraged to specify the kind of involvement that will be developed in Year 1, 2, or 3 (or 4 or 5 if the process is lengthened). Throughout the development process, educators must ask, "How might *more* parents, *different* parents, or *all* parents be involved or better informed?" Effective home-school collaboration programs and policies are based on the notion of shared responsibility for educational outcomes; therefore, the roles of the state department of education, school district administration, educators, parents, and students are specified. It is essential for school psychologists who provide the necessary leadership in this area to be knowledgeable about different strategies. These strategies need to be tailored to the needs of parents and educators at each school site. Furthermore, according to Epstein (1992), school psychologists would have to draw upon several roles and skills, including synthesizer of information about home-school collaboration at each grade level; disseminator of good ideas to assist the team to improve practice; coordinator of plans for action, including multiyear plans; facilitator/trainer to support educators' implementation of new programs; demonstrator of promising and successful practices; communicator with parents; and evaluator of programs. Throughout the process, parents and educators must realize that home-school collaboration is not an end but a means to the end of promoting student success and positive attitudes towards learning.

Training of teachers and administrators in practices that reach out to all families is an essential prerequisite and a viable role for school psychologists. The major point is that for home-school partnerships to promote student success a concerted effort and leadership are required. While they do not happen automatically, there is solid literature base and resources to provide the basis for successful implementation of such programs.

In closing, a question must be addressed: *What do school psychologists need to support home-school collaboration?* Two responses come to mind: administrator support and personal interest. The commitment and support of the building administration (principal) is essential. School psychologists would be wise to inform principals and administrators of the importance of developing meaningful parent involvement in education as a way to increase students' learning opportunities and progress. The eighth National Educational Goal is: Every school will promote partnerships that will increase parental involvement and participation in promoting social, emotional, and academic growth of children. Therefore, school psychologists' discussions with principals would be timely, and perhaps a fortuitous way to expand one's role. The degree to which the principal is supportive will influence both the teacher's perceptions and time availability of the school psychologist to these efforts.

Second, personal interest and commitment by the school psychologist is integral to the efficacy of home-school collaboration. To move from talk to action requires more than a knowledge base about implementation of programs. It will, at a minimum, require administrative support for and personal interest by school psychologists for home-school collaboration.

SUMMARY

Although home-school partnerships to enhance student learning are not the norm, there is much rhetoric and interest in developing partnerships. In this chapter, the positive outcomes for all key stakeholders, particularly students, were used to provide the rationale for creating home-school partnerships for the success of all students. Features of, barriers to, and principles of home-school cices were described in terms of (a) *content* knowledge for guidelines supporting home–school collaboration were described. Best practnowledge for guidelines supporting home-school collaboration and home-school collaboration strategies, and (b) *process* knowledge for developing programs. Best practices are characterized by viewing parents as partners in — not problems for — the success of students. To this end, educators are challenged in this chapter to view parents as their allies, which requires them to (a) ask parents to become involved and share responsibility for their children's education, (b) admit help is needed to resolve some school-based concerns, (c) change their beliefs about parents described as at-risk or uninvolved, (d) overcome barriers that maintain distance, and (e) engage in strategies that reach out to families. Home-school partnerships to enhance student learning will become the norm when a concerted effort is made to engage parents and educators in sharing goals, information, decision making, resources, and accountability for students' educational progress.

ANNOTATED BIBLIOGRAPHY

Christenson, S. L., & Conoley, J. C. (Eds.). (1992). *Home-school collaboration: Enhancing children's academic and social competence*. Silver Spring, MD: National Association of School Psychologists.
In this 24-chapter book, programs and models for the 1990s are provided in 8 chapters and practical approaches for use with different populations and concerns are described in 12 chapters. In the remaining chapters, the theoretical and empirical bases for developing partnerships, community resources, and leadership roles for school psychologists are described.

Fruchter, N., Galetta, A., & White, J. L. (1992). *New directions in parent involvement*. Washington, DC: Academy for Educational Development, Inc.
The results of a study examining new directions in parent involvement in school districts across the country are reported. Eighteen recently developed programs or reforms for preschool through grade 12 are described and include such programs as Comer's School Development Program, Levin's Accelerated Schools Program, Davies's League of Schools Reaching Out, Parents as Teachers (PAT) program, Megaskills Program, and others. Excellent reference and resource lists are provided.

Liontos, L. B. (1992). *At-risk families & schools: Becoming partners*. Eugene, OR: ERIC Clearinghouse on Educational Management, College of Education, University of Oregon.
This 150-page manual is an excellent, readable synthesis of theory, research, and specific programs about home-school collaboration for at-risk populations. Topics include communication, home as an educative environment, school readiness, home learning, and decision making. Particular emphasis is placed on early intervention, dropout prevention, and supporting and strengthening families. Elements of successful programs and information on reaching families is detailed.

Moles, O. C. (1993). *Building home-school partnerships for learning: Workshops for urban educators*. Washington, DC: U.S. Department of Education, Office of Educational Research and Improvement (OERI).
This sourcebook is designed to give educators new information and strategies for working with parents and to strengthen learning activities at home that support learning at school. It contains five workshops and related materials for local staff development activities in elementary and middle schools. Topics include family life, school programs and teacher practice, and district policies that facilitate home-school partnerships. Although the sourcebook is directed to urban educators, the material applies equally well to suburban and rural education.

Rioux, J. W., & Berla, N. (1993). *Innovations in parent and family involvement*. Princeton, NJ: Eye on Education.
This is an unusual and exciting resource for school psychologists who want to learn about school-based programs to involve families. Thirty-four programs, including preschool (N = 5), elementary (N = 11), middle school (N = 5), high school (N = 5), and district wide (N = 8) are described. Common characteristics of successful programs are explicated. They include, but are not restricted to, rejection of a deficit model outlook, expanding roles for professionals, and developing parents' skills and knowledge.

Swap, S. M. (1993). *Developing home-school partnerships: From concepts to practice*. New York: Teachers College Press.
Background information includes the benefits of parent involvement, barriers to parent involvement, and models of home-school relationships. Based on a new vision for a partnership model, Swap articulates two-way communication, conferencing, shared decision-making, and home-support-for-learning strategies. Strategies for developing partnerships on a limited basis and in a comprehensive fashion are also described.

Best Practices in Building-Level Public Relations

Carol Kelly
Jefferson County (Colorado) Schools

OVERVIEW

Ongoing public relations efforts at the building level are an integral, vital part of the school psychologist's role. Lack of clear communication can lead to misunderstanding, criticism, and poor support for important initiatives on behalf of children. This chapter provides the practitioner with ideas and information necessary for starting or improving building-level public relations efforts. The need for developing support for services, an explanation of fundamental concepts, a planning process, suggested activities, and skills for working with the media are discussed.

The purpose of public relations for school psychologists is to create understanding and good will between us and our various publics, upon whose support we are dependent. For us to continue to provide services to children, we must let parents, fellow educators, and community members know what we are doing and what we can do. Public relations provides knowledge that will allow us to effectively advocate for changes and impact education.

Public image is a major factor in determining the role we play and the services we can provide. In 1952 Edward Bernays, the father of public relations, pointed out that educational improvement efforts were dependent upon a better public understanding of schools. Pollster George Gallup (1982) stated that one of the biggest challenges educators faced was to let people know about the quality things being done in the schools.

The Need for Public Relations Efforts

Educators are all faced with "new realities" in relating to their communities. These include people with no credentials who have public credibility and credibility in the news media; highly trained professionals who must constantly prove their worth; reporters who seem intentionally to misuse facts and data; standards which are "unachievable"; and people who are "unconvincible" (Lukaszewski, 1992). Materials are increasingly being circulated critical of school programs, and in many communities citizens are becoming more vocal about initiatives to increase standards or improve student achievement. Programs to increase self-esteem or tolerance for multicultural diversity may be subject to special scrutiny.

Because confidence in public education is eroding and the competition for public funds is fierce, district budget allocations are under close public scrutiny. Services that decision makers know the least about are most often the first to go. Therefore, any position that is not solidified is in jeopardy.

People survive who add value to an organization. Adding value and being able to demonstrate accountability, however, are not enough. What is most critical are the perceptions that others have about a person's value. We must work to let others know how we are helping schools prepare children to be successful in the 21st century and find ways to productively involve our communities in designing services.

We cannot help children succeed if we are not around. As long as there are parents, board members, business people, legislators, and other members of the voting public who do not understand our goals, skills, and competencies, building support for our services is necessary.

Communicating with and involving a broad range of people leads to quality school psychological services. When lines of communication are open between us and our school communities, we are better able to ascertain local needs and issues and improve services to children accordingly.

Attitudes and perceptions about school psychologists are determined at the local building level. Public relations efforts at the district, state, or national level serve to reinforce attitudes that have been put in place by school psychologists in the buildings they serve.

Our profession will be perceived as a proactive contributing force in enhancing the overall quality of American education to the extent that we establish strong relationships with key audiences at the local level. It is incumbent that every school psychologist design a plan of action to gain public support. No one can do this for us.

Defining Planned Communication

Public relations begins with quality services to children. It is not a coverup or substitute for excellence. Communications efforts cannot convince anyone for very long that a good job is being done if it is not.

The National School Public Relations Association (1982) offers the following definition: *Public relations is a planned and systematic two-way process of communication between an educational organization and its internal and external publics. It is a plan of action to encourage public involvement and to earn public understanding and support* (p. 2).

John Wherry (1988), former executive director of the National School Public Relations Association, stated that the term *public relations* was synonymous with the *practice of social responsibility*, or doing the right thing in the public interest. He summed up public relations this way: *Do an effective job and let people know about the successes and challenges.*

BASIC CONSIDERATIONS

To implement successful public relations efforts, the school psychologist needs commitment along with understanding of fundamental concepts. This section covers identification of key publics, communication techniques, and issues management.

Identifying Key Publics

It is useful to think not in vague terms of *the general public*, but of essential audiences with whom relationships should be improved and maintained. The most effective approach can best be determined when considering the needs and interests of specific individuals or groups. As Lukaszewski (1992) put it, "the key to impact is audience focus — getting your message directly and clearly to the people who want and need to know your point of view."

Internal publics are those inside the school family: professionals and support staff including teachers, students, administrators, secretaries, substitutes, custodians, board members, teacher assistants, and student teachers.

According to public relations veterans, the initial step in initiating any public relations effort is to *start internally.* Community members listen to and trust information that comes directly from people who spend time working in the school. Plus, family members of educators and school psychologists can be indispensable resources. They often interact with a wide range of individuals and can help build support for services and children.

By involving and communicating with internal publics, we build a foundation that can increase our success in working on behalf of children with the larger community. Although audiences within the school family can lend invaluable support to efforts, they can just as easily undermine them. Credibility is established when quality services are provided and strong relationships are maintained with those you directly serve.

External audiences are those who work outside the school, or have a more indirect association. These include parents, community agencies, churches, legislators, civic organizations, senior citizens, the business community, and realtors. Most external public relations efforts focus on parents.

Though parents are a critical group, educators need to keep in mind that nearly three-fourths of American households have no children in school and that there are fewer school-age children than senior citizens. It should come as no surprise then that voters and taxpayers are increasingly interested in the costs associated with maintaining quality education and somewhat skeptical of teaching methods and services different from what they experienced when they were in school.

Communication efforts with external audiences will usually result in a more positive attitude toward support services in the schools. An informed public is more apt to support schools than not to support them (Kindred, Bagin, & Gallagher, 1984). Ledell and Arnsparger (1993) noted that communicating well and involving the community in restructuring efforts makes change less difficult for everyone.

Direct Personal Communication is Key

Interpersonal communication requires face-to-face interaction between two people and is necessary for influencing attitudes. Persuasion requires that direct person-to-person communication is maintained between us, school leaders, and influential publics. Studies show that people who acquire their information about the schools directly from board members and school employees tend to support the schools more than people who get their information from other sources (Kindred et al., 1984). When people think about planning a vacation to a new place, for example, they tend to rely more on a trusted neighbor's opinion than a glossy travel brochure. We have more confidence in people with whom a relationship has been established.

Examples of situations that involve interpersonal communication include child-study-team meetings, back-to-school night, parent conferences, faculty presentations, phone calls, and talks delivered to small groups. Settings where interpersonal relationships can be established include athletic clubs, beauty salons, civic organization meetings, social events, grocery stores, and golf courses. *Any* interaction with other people is an opportunity to build a relationship that can lead to invaluable support for services.

When using interpersonal communication, be aware of both your personal communication style and that of the receiver. Your approach should vary depending upon whether you are talking to a progressive administrator, a skeptical parent, an insecure teacher, or a school board member who does not understand the need for support services in the schools. Does the person have a hidden agenda or anger that must be diffused? Begin by listening to the other person's perceptions. Be sensitive to cultural differences.

Trusting relationships form the basis for mutually supportive behavior. Essential elements for such relationships include authenticity, credibility, and trust. People develop confidence in you when you demonstrate expertise in your field and display understanding of viewpoints different from your own.

Mass communication techniques are useful for imparting information, making people aware of a specific situation, or reinforcing attitudes. Examples include newsletters, public service announcements, radio and television appearances, advertising, parent handouts, films, posters, and brochures.

Relying extensively on such sources, as opposed to more direct communication approaches, is a major mistake of many districts and educational associations. These strategies inform people, but do little to influence opinions or change behavior.

Be an Issues Manager

Issues management is a concept that cannot be overlooked when building support for services. For us to be successful, we must be aware of our customers, the voting public, and keep up with their thinking. Radical shifts in society create dilemmas that become issues. It may be necessary to readjust services to coincide with shirting public interests.

Planning from the issues, rather than being managed by them, allows us to take more control over the future. It requires a decisive approach and awareness of relevant community problems and trends. Key issues are the vehicle through which we reach our audiences, and our response to issues strongly shapes perceptions others have about us.

To stay current with the issues, scan publications that are read in the school community, maintain links with parent groups, visit the faculty lounge, and subscribe to periodicals such as *Education Week* and the *Kappan*. Look for concerns that you can do something about and that will make you more effective in meeting the needs of children.

Form *issues applications* teams with other members of the school community. Individuals review topics covered in local papers or discussed in the neighborhood related to education and children. Issues being addressed in other districts or states that could be of concern to the local district are anticipated.

William Banach of the Institute for Future Studies regularly releases *Critical Issues Facing America's Public Schools*, many of which have direct relation to school psychological services. On the forefront of many school agendas are student violence, the change process, lack of family experience for children, national standards, tuition vouchers, economic inequities, accountability, racial tension, and school reform.

Look for issues that will make you more valuable to other educators and to children. Watch where education, your district, and your individual schools are headed, how schools are responding, and how leaders are managing change. Look at the unique competencies that you have to help schools reach their objectives. Link your skills with directions your schools and communities are taking.

With renewed interest in children and public education at the national level, there is a momentum to help our country and districts shift their priorities on behalf of children and defend educational quality for all children.

With an issues-management approach, we cannot be bound by the job description. Services are designed around community needs. Efforts could include organizing a conflict resolution program, offering a parenting class, working on a school improvement committee, or developing a plan with the principal to help the staff adapt to change. The best efforts are aligned with school goals to boost parent involvement, create a safe learning environment, or improve student achievement. Responding constructively to local needs will result in a positive attitude from the staff and community and help build support for services to children.

BEST PRACTICES

This section outlines a public relations planning process, presents suggested activities to communicate to various audiences, and offers tips for working with the media.

Getting Started

An ongoing 4-step planning process will ensure that time and energy are strategically directed to building essential relationships. Effective planning is required to secure the future of quality mental health services for children. A planned approach for reaching out to people will be more efficient than implementing ideas from someone else's list or, worse, responding only to difficult crisis situations such as a proposal to reduce support staff.

The likelihood of developing workable, effective plans is increased when others are involved in the process. Put together a team and consult with colleagues, your school principals, and your supervisor throughout the process.

Step One. The first step consists of listening and conducting an *analysis* of where you are now. What individuals and groups are you already talking to, what is important to them, and what are current perceptions? It is likely that you already are promoting school psychology in many ways.

Identify audiences being reached through current efforts. Consider why communication with these people is important and the effectiveness of present efforts. List additional audiences with whom you would like to communicate. Decide what they need to know, what current perceptions are, and what you would like them to be.

Think about people who can help you meet your goals as well as those that can hurt or stop efforts. Which audiences may be uninformed about how school psychology contributes to education? Are there groups that have negative preconceived attitudes toward the profession?

Establish ongoing avenues of communication to directly determine perceptions, priorities, and concerns others have about your services. Listen to what teachers, parents, students, administrators, and other consumers of our services have to say. What do they want from psychologists and what are they willing to pay for?

Among your targeted groups, be sure to establish two-way communication with *opinion leaders* in the school community who care about support services for children. Opinion leaders are those influential role models whom others seek out for advice and who lead public opinion.

A helpful tool in this beginning step is a *communication grid.* List target audiences across the top of a page. Write ongoing activities down the left side. Check all groups that are reached by each activity. For example, a regular article in the school's newsletter may be read by parents, teachers, administrators, and support staff. The grid will help you take inventory of current activities and reveal where special efforts are needed.

A brief needs assessment is essential for making appropriate decisions. Many schools conduct annual community surveys. Request that a question about psychological services be included. Or, your department might want to develop its own survey. What perceptions do people we work with and community members have? Are others aware of the broad range of services provided? What are major concerns and expectations? Survey results can provide a solid base for your plan of action and goals of service.

Before designing specific plans, find out all you can about your school community. Consider factors such as the number of residents without children in school, voting patterns, educational background, income levels, mobility and employment patterns. How does the community view the school?

Step Two. It is essential to *plan:* Determine which audiences to focus upon and how you can most directly communicate with them. Will you adequately influence your selected groups through newspapers and brochures, or will you need to meet personally with individuals?

Set measurable objectives. Do you want to impart knowledge, improve perceptions and attitudes, or change behaviors? Goals may be for the hiring of additional psychologists or more cooperation from teachers. Think about your desired future versus your predicted future.

Establish time lines and ascertain any costs associated with your plans. School district communications officers, state school public relations associations, and the National Association of School Psychologists (NASP) may be able to provide expertise and materials specific to your situation; use them to your advantage. It may be possible to coordinate your activities with plans that your building, district, or state association is already implementing.

It will not be possible to design strategies that meet every need. *"Supertarget"* audiences most affected by what you are doing and who are most critical for support. While efforts will focus on these key groups, you may be able to maintain relationships with others through less frequent contacts. These relationships will result in a better reputation and can ensure that your interests will be considered when decisions affecting services to children surface.

Consider a *marketing* approach. When you are interacting with members of identified audiences, emphasize how school psychological services can support their goals. We must understand what is important to people and describe ourselves in terms that relate to their priorities. Tell how school psychologists help teachers improve student achievement, help administrators implement conflict resolution programs, or help parents become effective partners with the school. When messages are *personalized* and *relevant* to an individual, they are listened to with more interest.

Determine which strategies will most likely help meet objectives for each group. Develop an organized plan about how you can best communicate your needs and improve services for children.

Step Three. The next step is *implementation*, or carrying out plans. The most effective plans emphasize face-to-face interpersonal relationships and minimize the role of the media. People programs beat paper programs every time. Persuasion comes through the time-consuming and hard work of meeting with staff and key influential audiences (Bagin, 1993). Persistent one-on-one efforts are what influence attitudes, develop better understandings, and change behaviors. Be sure to maintain interaction with supporters and find ways they can actively promote your objectives.

Step Four. Finally, communications efforts need to be *evaluated*. Look at your original objectives and determine how successful you were. Many schools may be used for obtaining feedback; for the most reliable information, use a variety of sources.

A rigorous scientific system is not necessary to get accurate information. Informally evaluate the success of your plans by analyzing behavior toward school psychological services. Do students refer classmates in need? Did the community oppose a district proposal to reduce psychological services? Do parents express appreciation of your services and give your name to friends whose children may be having difficulties? Are you invited to be present at school board meetings? Keep a file of written feedback you receive.

Attend to negative feedback and look for ways to address concerns in new plans. Invite those who have concerns to brainstorm alternative with you. Identify modifications that need to be made in the future. Based on your findings, activities may be maintained, deleted, added, or modified.

This cycle may be repeated each school year. When efforts have been evaluated, go back to Step One. Influencing attitudes is an ongoing process. Reevaluate and modify plans on a continuing basis.

A Menu of Suggested Ideas

The following activities are designed to build positive relationships with parents, administrators, teachers, support staff, students, and the local community. Though organized around selected audiences, much overlap exists. For example, an activity listed under the parent section may also reach teachers and administrators. Coordinate activities into your overall plan.

Psychologists.

- Start with your own group first. Prepare a district plan to increase support. Develop ongoing communication strategies such as regular meetings, newsletters, or phone trees.
- Select a cadre of district and community leaders. Establish relationships, ask for perceptions, and involve them in planning your services.
- Involve family members of school psychologists in building support and communicating your message.

Teachers.

- Greet teachers and other staff members each day by name.
- Eat lunch with teachers. Vary your lunch period to socialize with more staff.
- Introduce yourself at a beginning-of-the-year faculty meeting. In new assignments, let the staff know how best to serve your services.
- Involve teachers in plans relating to your services with students.
- Give presentations to the faculty. Consider topics such as parent conferences, teacher stress, and classroom meetings.
- During School Psychology Week, show others your appreciation of their support. Bring refreshment to the lounge or send notes of appreciation.
- Be a part of the school family. Attend faculty meetings and school social functions. Know your school's mission and find ways to help reach school goals.
- Hold regular, open office hours.
- Help teachers manage district- and school-change efforts.
- Volunteer to serve on building committees. Consider community relations or a school improvement group.

Parents.

- Cultivate a group of parent supporters. Meet with them regularly and seek opinions about your services. Third-party advocacy can be invaluable.
- Make yourself visible. Circulate at school functions such as back-to-school nights, open houses, special events, and social activities.
- Distribute handouts on common areas of interest such as self-esteem, study skills, and stress. Use NASP *Communiqué* parent handouts.
- Project a professional image: Use business cards, hang diplomas and awards, and dress in a professional manner.
- Make regular phone calls to parents of children on your caseload. Commend them for their efforts and keep them posted on their children's accomplishments.
- Be sensitive to the fact that parents from other countries may not understand everything you are saying. Learn about cultural norms of diverse community groups.
- Actively involve parents in your service delivery.
- Write a regular school newsletter column.
- Maintain a flexible schedule for meetings with parents unable to come in during school hours. Include fathers and stepparents.
- Make home- or work-site visits when parents cannot or will not come to the school.

- Return phone calls promptly — within 24 hours whenever possible.
- Establish a liaison with your parent-teacher organizations.
- Welcome opportunities to talk to parent groups. They are always interested in learning ways to help improve their child's school performance. Do not wait to be invited.
- Work with the PTA to develop a parent shelf in the school library. Write book reviews in the school newsletter.
- Offer a parenting class.
- Communicate in simple language. You will not build confidence when people cannot understand you. Avoid jargon in reports and in face-to-face meetings.

Students.

- Maintain quality services and positive, caring day-to-day relationships. Community opinions are largely reflective of student comments about school.
- Make presentations about your services to students.
- Sponsor a student group such as student council, honor society, or an athletics team.
- Help develop and participate in student recognition programs.
- Send congratulatory notes or "happy grams."
- Continue to develop yourself and your skills by attending classes, taking workshops, and consulting with colleagues.
- Make positive referrals to the principal when students have been successful.
- Greet students by name around the building and in the halls. Walk through the lunch room from time to time.
- Attend special events such as plays, field trips, assemblies, and award presentations.
- Consider alternative settings for sessions with students. Take a walk, sit on the swings, shoot baskets, or meet for lunch.
- Take students out to lunch when they have accomplished a major goal. Let them invite classmates.

School community.

- Become a visible, indispensable resource. Let community members know what the problems and issues are that children face and how your services help.
- Write letters to the editor, guest opinions, or editorials about community issues for the local newspaper.
- Patronize local businesses, including those run by students' parents.
- Volunteer to be a guest and answer questions on radio call-in shows.
- Know the facts about your schools and district: board members, demographics, board policies, test scores, and district strengths and weaknesses.
- Nominate individuals for district, state, or national recognitions.
- Develop a plan so district psychologists are represented in community organizations.
- Become involved in community activities such as crime-prevention programs, church groups, sports programs, or service groups.
- Integrate school psychology activities and information into American Education Week events.
- Arrange media or newspaper coverage of special projects or events.
- Work with other service providers to sponsor a Saturday family workshop with a selection of speakers on various topics of interest to the community.

Administrators.

- Establish a positive working relationship with your school's leaders. Find out their interests and strengths.
- Develop a relationship with your superintendent. Make sure that he or she knows your competencies and find ways to work together.
- Keep administrators abreast of your activities.
- Work with your principal in areas of mutual concern such as conflict mediation, effective discipline, crisis intervention, or improving student achievement.
- Do not set yourself up for failure. Underpromise and overdeliver. Meet deadlines early and anticipate school needs.
- Regularly attend school board meetings. Positively involve board members in meeting needs of students in your district. Coordinate your efforts with those of board directions.

Support staff.

- Keep in mind that the best-known people in the school are usually nonprofessionals: bus drivers, custodians, and secretaries who often live in the neighborhood.

- Secretaries talk to more people in a month than most people do in a year; they are the "voice" of your school. Develop good relationships.
- Offer a behavior management inservice for teacher assistants.
- Participate in appreciation days and events for support staff members.
- Recognize any special efforts.

Public Speaking and Interviews

An effective strategy for fostering positive relationships is making small-group presentations to teachers, parents, board meetings, or community groups. You may also decide that television or radio interviews will help tell your story to key publics. The following suggestions will help you present yourself as an effective and credible information source.

- Enroll in a public speaking course or group like Toastmasters to hone your skills. In the process, you will educate fellow members who can go forth and tell your story.
- Know your topic. Always take time to thoroughly prepare. Avoid *on the spot* interviews or presentations unless you are very knowledgeable about the subject.
- Learn the technique of *bridging:* taking the conversation from where the interviewer may try to direct it to where you want it to go.
- Consider factors relating to your audience such as education level, cultural diversity, age, and income level.
- Make presentations on topics of interest to your audience. A talk on school psychology, per se, will usually not be of much concern.
- Anticipate information your source will want to know. If possible, find out what questions will be asked. Prepare an organized information sheet.
- Even in a crisis situation, ask if you can call back in half an hour so that you can gather your thoughts and information. Outline the course of action being taken.
- Be honest. Admit problems and state what is being done to address them.
- Do say "I don't know" rather than bluff your way through a response. Offer to find the information.
- Maintain eye contact with your audience or interviewer, not a television camera.
- Never speculate or answer "what if" questions.
- Pause when collecting your thoughts. Ask to have any "uhs" or "ahs" you may inadvertently say edited from recorded interviews.
- Eliminate jargon, accusations, and negative comments.
- Respond to questions with positive, complete quotable statements. Prepare 3-second quotes before the interview.
- Do not say "no comment" or "off the record." Give a valid reason for declining to comment, such as safety or maintaining confidentiality. If you do not want to hear or read about it, do not say it.
- Smile. Be excited about your topic. Use a warm and caring tone. Keep your hands at your side. Gesture to emphasize points, but do not overdo.
- Tape yourself, both when you practice and when you present.
- Present yourself as a credible source. Do not wear clothes that might distract from your message.
- Recognize what is remembered in any presentation or conversation: appearance, 55%; voice, 38%; and content, 7%.

Working with the Media

Using the media to win people over is no substitute for working directly with those you want to influence. When you use the media, your message becomes at risk of being modified, taken out of context, or put into an emotional backdrop.

At times, however, it is likely that it may be in your best interest to communicate with the community through the media as part of a support strategy to provide information or reinforce attitudes. This is one of the primary ways parents and people without children learn about the school.

The first step in establishing a relationship with the local media is finding out who covers educational news in your community. Call local newspaper, television, or radio stations directly for this information. Your district public relations office may provide contacts, assist with news releases, or arrange for media coverage of events.

The media can build support for services by sending reporters to cover programs such as divorce groups, safe school programs, or social skills units. News sources can provide advance publicity about upcoming events such as parenting classes or talks to a local civic group. Academic success, learning difficulties, discipline, and other issues school psychologists address make for interesting feature story topics.

What is news? Good publicity depends on knowing what makes good news. You are the best judge of which issues are of interest to the community. A key concept in story ideas is *timeliness.* Think of stories that are related to the time of year. Summer vacation activities, holiday pressures, children's fears (Halloween), adapting to a new school at the beginning of the school year, and middle school adjustment are a few examples. Do not forget to tie into national events and trends. Let people know what school psychologists are doing to address issues.

You might send in news releases when you attend a convention, initiate a new program, receive a special award, or are elected to a position in your professional association.

News releases. The most common way of letting the media know about upcoming events is by sending a news release. Use the following guidelines to increase the likelihood of getting a favorable response.

- Send out releases 10 days to 2 weeks prior to any event. Mail it to a specific person.
- Send the release on school stationery or a district news release form.
- Keep your message brief and concise. Omit needless words. Use the active voice.
- Releases should be typewritten, double-spaced on standard size paper. Use only one side and keep the release to one page. Use wide margins to allow for editing.
- Indent paragraphs. Include no more than two to three sentences in each. Longer paragraphs lose readers. Justify the left margin only.
- Use the *inverted pyramid* style. Include the "who," "what," "when," "where," and "how" in the first paragraph. Following this quick summary of major facts, include information in descending order of importance. This allows editors to cut from the bottom without having to rewrite it.
- Use first and last names: "Dr. Pat Harrison received the award," not "Harrison" or "Dr. Harrison."
- Eliminate jargon and write out any acronyms.
- Write releases in the third person, avoiding the use of first-person references such as "we," "our," and "your."
- Include a fact sheet about your school or school psychology association.
- For best readability, write at or below the 9th grade level. Fewer than 10 words out of 100 should have more than three syllables.
- Sentences should be short. The average length for best readability is no more than 19 words.
- Designate the end of the release with "# # #" centered. Clearly indicate the name of a person to contact for further information along with home and work phone numbers. Reporters often work day and evening hours.

When coverage is provided, send a note of appreciation. Papers and news broadcasts often have limited space and competition is keen.

SUMMARY

Establishing strong personalized relationships with audiences within the school community is essential. Attitudes that parents, community members, and educators hold about school psychological services are determined at the local building level. Influencing public attitudes is a continual process. Our challenge is to carefully identify key decision makers and meet with them directly so that they can join us in taking action on behalf of children.

Planned two-way communication creates understanding and support of the assistance our profession provides to children and education. The delivery of quality services to students is a prerequisite for successful public relations efforts.

A development and implementation cycle should be an ongoing part of every school psychologist's yearly routine. As a first step, current efforts are examined and information about the local school community is gathered. Priority audiences are then targeted along with the information each group needs to know and supportive action they can take. After planning and executing programs, feedback is secured and effectiveness of efforts is evaluated.

Every school psychologist must communicate with and involve a variety of people in his or her local community. The profession will be able to assume a leadership role in helping schools better meet the needs of all children to the extent that we work with others and build confidence in the services we provide.

AUTHOR'S NOTE

Pat Jackson of Jackson, Jackson, and Wagner is acknowledged for his contributions.

Best Practices in Communicating with Parents

Paula Sachs Wise
Western Illinois University

OVERVIEW

Imagine that you are invited to attend a meeting of the State Board of Education regarding the status of school psychology in your state. You are the only school psychologist invited to attend the meeting. In fact, you are the only non-board-member in attendance at the meeting. The board members have worked together for a long time. They throw terms around with which you are unfamiliar, tell "private jokes" that you don't understand, present data about school psychology that you are unprepared to substantiate or refute, and smile rather condescendingly at you when you make a comment. The board members unanimously conclude that school psychological services in the state are woefully inadequate and should either be improved or dropped. A paper is then passed around to be signed by the board members and by you to show consensus. Everyone watches you to see if you will sign. Feeling tremendous pressure to conform, even though you are also feeling uncomfortable and depressed, you go along with the board since you have no "cold hard facts" on hand to refute their findings.

Not a very comfortable feeling is it? Especially when the meeting is about the fate of something you hold near and dear to you, like the profession of school psychology. You leave the meeting disgusted with the board for being so strong and disgusted with yourself for being so weak. You feel as though you have let school psychology down.

Now imagine you are a parent at a multidisciplinary staffing. Around the table sit a group of professional educators, most of whom know each other well and have worked together for a long time. You are the only non-school person in attendance. The topic of discussion is your child's educational future. Test results are presented and discussed and everyone else at the table seems to understand the results, but you don't know a processing deficit from an attention deficit. If all of these educators think that your child belongs in a learning disabilities resource room, who are you to disagree? Such a staffing represents what we might call the "worst practices in communicating with parents" because there is little genuine communication occurring.

The focus of this chapter is on the usefulness, the feasibility, and the importance of improving school psychologists' communications with parents. Some of the topics to be discussed include

- Why good communication between school psychologists and parents can benefit children.
- How good communication between school psychologists and parents can benefit children.
- How school psychologist–parent communication fits into the various roles and functions of the school psychologist.

In addition, references will be provided to assist school psychologists in communicating more effectively with different "types" of parents (e.g., parents new to special education, angry parents). Finally, general guidelines will be provided to facilitate school psychologists' improved communication with parents.

BASIC CONSIDERATIONS

Communicating frequently and effectively with parents should be as important a part of the school psychologist's job as assessing students and consulting with teachers. The passage of PL 94-142 in 1975 was touted by parents, special educators, and school psychologists alike as having the potential to lead to dramatic improvement in parents' involvement in the educational placement and programming of their children with disabilities. Yet while parents of children with disabilities have become more identified as team members in multidisciplinary staffings over the last few years, they have lost some ground as well. Since 1975 when staffings replaced parent conferences as the primary forum for the presentation of assessment results and the discussion of intervention strategies, parents have lost some of their unique privileges as parents while gaining rights as multidisciplinary team members.

Several years after the passage of PL 94-142, participants at the Olympia Conference on the Future of School Psychology emphasized school psychologists' relationships with parents as a major area to address (Brown & Cardon, 1982). At that conference, "concern was expressed that school psychologists have not been clearly recognized by the public as parent advocates. It was recommended that in matters relating to child welfare that parents and school psychologists merge their efforts in legislative and political action" (Brown & Cardon, 1982, p. 195). Yet as recently as 1991, a random sample of school psychologists in New York State reported spending an average of only 39.4 minutes (or 8%) of their days with family members of children in their schools (Fish & Massey, 1991). Of the 39.4 minutes per day, 40% was spent in telephone conversations, 30% in meetings with other people present, and 4% was spent writing notes to family members. Only 24% of the 39.4 minutes (9.5 minutes) was spent in individual meetings between the school psychologist and a child's family members. Fish and Massey also noted that of the total number of contacts with family members, 71% involved the mother only, 16.6% involved both parents, and 6.6% involved the father only. Fish and Massey suggested that more efforts be made to include fathers and other family members, and to increase the number of direct school psychologist-family contacts (without others present) in order to enhance school psychologist-family working relationships.

Why Good Communication Between School Psychologists and Parents is Important

School psychologist–parent communication provides the opportunity for the school psychologist to share information with the parent. When a child is first identified as being in need of psychological services, it is important to answer the parents' questions and provide general information. Specifically, the school psychologist needs to inform the parents as to the reason for the referral, the types of procedures that will be followed, the timeline that the parents can expect, the possible outcomes of the assessment, and the parents' rights and responsibilities in the assessment process. Parents should also have an opportunity to ask questions about these procedural issues.

Following an individual assessment of a child, parents generally wish to know, "How did my child do? Is my child 'normal'? What are his strengths and weaknesses? What can I expect from her? What should I do when he misbehaves?" (Wise, 1986, p. 7). Again, parents should have an opportunity to ask questions, request clarification, and understand in general terms the possible implications of your findings, keeping in mind that decisions are actually made during the multidisciplinary staffing. Parents who are informed of assessment results prior to the multidisciplinary staffing may be better able to act as contributing members of the multidisciplinary team (Teglasi, 1985). They have had time to digest and to ponder the assessment information and to formulate questions beforehand so that during the staffing they can ask their questions and make well thought out comments and suggestions.

School psychologist–parent communication provides the opportunity for the parent to "size up" the school psychologist and for the school psychologist to "size up" the parents. This is a frequently overlooked but important reason for school psychologist–parent conferences. Parents want to know: Who is this "shrink" who will be talking to my child? Does the person seem honest and trustworthy? Will my child like working with this person? Do I have confidence in the school psychologist's judgments? Does the school psychologist seem genuinely interested in and concerned about my child and about me? Not only do positive initial impressions ease the parents' mind, but parents who believe that the school psychologist is sincere and cares about them are more apt to carry out any eventual recommendations (Teglasi, 1985).

At the same time, school psychologists may use their initial contacts with parents to assess informally the child's family background, the degree of parental cooperation to expect, the parents' attitude about the child and the difficulties the child is having, as well as the parents' attitudes about the classroom teacher, the school system, and education in general. What are the parent's expectations for the child? Do these expectations seem realistic based upon the information already known? Is this a parent who would easily be able to complete a behavior questionnaire about the child? Will this parent follow through if asked to participate in intervention strategies? Just as every school psychology graduate student is taught the importance of establishing rapport with children, it is also important for school psychologists to establish rapport with parents!

School psychologist–parent communication provides the opportunity for parents to share information and concerns with the school psychologist. Who is better able to provide the school psychologist with information about developmental milestones, childhood illnesses and accidents, family stresses, and inter-sibling comparisons than the parents? How does the parent view the child and the difficulties that she is experiencing? What does the parent think are the child's strengths and weaknesses? What does the child say about school when he comes home? Were the parents aware of any problems prior to the referral? What is the child like at home? What does she like to do? Who does he play with? What activities is she involved in? What are his eating habits and sleeping habits? Are there any unusual stresses or strains in the child's life at present? What questions and concerns do the parents have that the teacher or other referral agent may not have mentioned?

Parents are generally their children's primary care givers and may be the one constant throughout the child's life. In all likelihood, they know more about the child than a teacher or other "temporary person" in the child's life. Why not rely upon parents for valuable information about the child? As noted by Sattler (1992), "Parents have a wealth of information about their child. A well-conducted parental interview will serve as a valuable source of information about the child and family and will lay the groundwork for enlisting parental cooperation with intervention efforts" (p. 429). Of course, it must be recognized that parents are far from unbiased observers of their children. Their viewpoints, however, are vital input for a thorough understanding of the child's difficulties.

Often, parents may be uncertain as to the teacher's reasons for referring their child. In fact, in one study (Knoff, 1982) when parents and school personnel were asked independently to identify the reasons for referral of a particular child from a checklist of 17 reasons, agreement between the parents and school personnel was found in only 57% of cases. Meeting with the parents prior to the gathering of other types of assessment data can provide the forum for clarification of any misconceptions the parents might have.

School psychologist–parent communication provides opportunities for parents and school psychologists to cooperate and collaborate — to view each other as allies rather than adversaries. If school psychologists truly want to achieve cooperative and collaborative relationships with parents, we must spend more time meeting with parents by themselves, away from the presence of other school personnel. Particularly in cases in which multidisciplinary staffings will likely result from our efforts, parents tend to be comforted by the fact that they have met with the school psychologist ahead of time and that there is at least one familiar and "friendly face" around the table — one person they have met before and whom they regard as an advocate for their child. Also if parents are hearing for the first time that their child has a disability of some type, they have the right to hear that news in a one-to-one meeting with the school psychologist, not in a large meeting with many strangers present. Parents' reactions to such news run the gamut from crying to yelling to shock (Sattler, 1992) but while the nature of the reaction may differ, the impact of such news on parents nearly always elicits a strong emotional response. Such emotional displays warrant a certain amount of privacy rather than a public forum.

Much has been written about the clientage issue within school psychology. That is, who is the client of the school psychologist? Pantaleno (1983) put forth the relatively extreme but thought-provoking notion that parents should be considered the primary clients of the school psychologist while children should be viewed as secondary clients. After all, parents not only provide us with children in need of our services but they also pay our salaries through their tax dollars. While others within the school system might have ulterior motives in referring a child for psychological services (e.g., getting the child out of a classroom or a school building), school psychologists tend to share the parents' motive to do whatever can be done to help the child.

Parents can also work with school psychologists as change agents in schools (Simpson & Poplin, 1982). Working together as child advocates, school psychologists can contribute their knowledge of how schools work and their awareness of current developments in school-related legislation and practices. Parents can contribute political clout through putting pressure on school officials, lobbying for legislation, and supporting local, state, and federal legislation with favorable platforms and voting records.

School psychologist–parent communication (in conjunction with school psychologist–teacher communication) may help bridge the gap between parents and teachers. When parents and teachers meet together each party may bring to the meeting a certain amount of "baggage" based upon what the child has said or done. A child may tell his parents how mean the teacher is, how she picks on him when others in the class are to blame, and how she refuses to answer his questions. The same child may tell his teacher that his parents let him stay up late watching R-rated movies or that he has so many home responsibilities with such severe consequences for noncompliance that he is unable to complete homework assignments.

The parent and teacher come to conferences with one another armed with these preconceived notions and immediately may be inclined to blame the other for the problems the child is experiencing. Parents may be convinced that the child's learning problems are a result of the teacher's unreasonable expectations, while the teacher may attribute the child's difficulties to a home environment neither supportive of nor conducive to education.

The school psychologist who understands that from an ecological perspective, the child's behavior is influenced by and influences the school *and* the home environment, can remain relatively neutral (Power & Bartholomew, 1985). Meeting individually with each party, the school psychologist can listen carefully, clarify terms and concerns, empathize with both, while still addressing the concerns in a nondefensive, realistic manner.

School psychologist–parent communication is necessary for compliance with legal and ethical guidelines (e.g., informed consent). There are several issues involved in communicating with parents that involve legal and ethical principles. The first contact many school psychologists have with parents may concern the need for the parents to consent to having their child receive psychological services. Informed consent is needed when assessment procedures are performed, individual or group counseling services are offered, research projects involve children, records are sent from the school to another professional or another school district, and so forth. Simply put, parents have a right to know what is going on with respect to their child in school especially if the child is treated differently in any way than his/her classmates. Jacob and Hartshorne (1991) note that parents must be provided with information regarding

> the nature and scope of services offered, assessment-treatment goals and procedures, the expected duration of services, any foreseeable risks or discomforts for the student-client (including any risks of psychological or physical harm), the cost of the services to the parent or student (if any), the benefits that can reasonably be expected, the possible consequences/risks of not receiving treatment/services, and information about alternative treatments/services that may be beneficial (p. 53)

In addition, parents must be provided with this information in an understandable manner. If the parents are non-English-speaking, for example, efforts must be made to find a way to communicate the information to the parents in their native language.

Parents have other legal rights as well. They have a right to review their children's academic records, a right to privacy, a right to confidentiality of the information they do choose to share, and a right to share information with or withhold information from other individuals and agencies. (See Fischer & Sorenson, 1991, and Jacob & Hartshorne, 1991, for further clarification of legal and ethical issues surrounding communication with parents.)

School psychologist–parent communication is important from a public relations standpoint. Those of us who work for school districts or other local, state, or national agencies are public figures. Our salaries are paid from tax monies, and we are accountable to the public for our professional activities. The more positive contacts we can have with parents, the more support we can probably hope for if our jobs are on the line or if a school referendum is up for a vote.

How Good School Psychologist–Parent Communication Can Benefit Children

There are several ways in which good communication between school psychologists and parents can benefit children. First, parents tend to pass their feelings about things to their children. If the parents believe that the school psychologist working with their child is likely to have a positive impact on the child's learning or behavior, then through the "self-fulfilling prophecy" or the power of positive thinking, the impact is more likely to occur.

Second, if the parents feel as though they are partners with the school psychologist and other school personnel and that they can help to make a difference in their children's school experiences, the parents may work harder to achieve results. To use a popular buzzword of the 1990s, the parents are "empowered" by their relationship with the school psychologist to take a more active role in their children's education. Thus parents may be more consistent in rewarding a child's good behavior, put forth extra effort in ignoring a child's inappropriate behaviors, or even take extra care in applying consequences when the child disobeys an established rule.

The Importance of Good School Psychologist–Parent Communication in Each of the Roles and Functions of the School Psychologist

In the traditional *child study or problem-solving assessment role*, the school psychologist needs to communicate with parents to obtain informed consent and background information as well as to provide parents with information about the assessment process, the timeline to be followed, and the possible outcomes of the assessment. In addition, parents may be asked to participate actively in the assessment process through completing behavior rating scales, personality inventories, and/or adaptive behavior inventories and collecting actual student performance data. Some problems that students experience in school may also be observable in the home environment. In such cases, parents can collect relevant data such as reading at home, completion of homework assignments, study habits, and so forth. On a less formal basis parents can be useful sources of information about children's study habits, reading practices, and other social and behavioral observations. Parents also function as part of the multidisciplinary team and in that role they participate in the information-sharing and decision-making processes as team members.

Of course not all school psychologist–parent communication is oral; written communication — memos, reports, and notices — are also worthy of consideration. Ross-Reynolds (1990) notes that "the fundamental purpose of reports is to communicate information to the referring person in such a way that the latter's beliefs, feelings, and/or behaviors relative to the child are changed" (p. 621). Reports have many other uses as well, including presenting and summarizing assessment data in a (usually) succinct manner, and providing a "hard copy" of results for teachers and parents to read at their leisure away from the distracting presence of other people. Ross-Reynolds's approach to report writing might be called an "action-oriented" approach focusing on interventions, actions, and outcomes rather than on the traditional rehashing of the psychologist's findings. It is also active because through his approach the psychologist is attempting to influence or change the reader in some ways.

A second innovative approach to report writing is put forward by Sandy (1986) who calls his method a "descriptive-collaborative approach." Sandy suggests that if school psychologists genuinely wish to have parents communicate their thoughts and feelings to us, we should not include our own interpretations of the data in the written report. Rather we should present assessment data, including some of the actual responses of the child. We should then, in conferences and/or staffings, encourage the parents and other participants to interpret the results and to provide examples of home and school behaviors similar to the test results. Sandy maintains that his approach is much more likely to lead to parents and others becoming increasingly active in identifying problems and suggesting and implementing interventions and that the approach also strengthens alliances rather than adversarial relationships between parents and school psychologists.

In the *intervention role*, parents are needed to provide consent for suggested interventions. They may also play an active role through such practices as being involved in the completion of daily school–home notes or providing reinforcements for appropriate behavior. Further, parents may be asked to carry out interventions, collect performance data, and assist with intervention decision making. Simpson and Poplin (1981) suggest a number of ways in which parents can be involved in behavioral interventions and provide a review of many successful programs described in the research literature.

In the *consultation role*, the parents are partners with school psychologists and other school personnel in the collaborative problem-solving process (Sheridan, Kratochwill, & Elliott, 1990). They may provide input into the problem, elaborate on the nature and scope of the difficulties, help to generate solutions, and implement the home-based part of the plan. Parents may also be involved in collecting data, completing behavior check lists, and providing reinforcements. Finally, in the consultation role, parents may be excellent sources of feedback as to how a plan is proceeding and what changes should or could be made to improve the results.

In the school psychologist's role as a *liaison between the schools and community agencies*, the school psychologist can provide a link between the parents, the school, and the agency, trying to match the child or the family up with appropriate services. Under some circumstances it may be appropriate for the school psychologist to make the initial contact with an outside agency in order to ease the parents' way for future contacts. The school psychologist may be a valuable source of information to the parents and to the school in providing information about available services, fees, waiting lists, procedures, and so forth. Parents who have had little experience with such services may not even know what questions to ask and thus may be intimidated from following through in order to receive much needed services.

In the school psychologist's role as a *researcher*, parental cooperation and involvement is often critical. Not only will parents be asked to give informal consent if their child is asked to participate in a research project, the parents may also be asked to complete questionnaires about the family background, the home environment, or school-related experiences depending upon the nature of the project. All school psychologists, whether or not they take an active role in conducting research, should be involved as consumers of relevant research. For example, relevant to the area of communicating with parents, recent research has identified family-related variables that relate to school achievement (Christenson, Rounds, & Gorney, 1992). Based upon this research it has been suggested

> that school psychologists need to (a) be knowledgeable about family influences on student achievement, (b) assess the degree to which children's home environments are characterized by factors correlated with achievement, (c) promote recommended practices for involving parents in education, and (d) design home-school interventions that address students' learning. (Christenson, Rounds, & Gorney, 1992, p. 198)

BEST PRACTICES IN COMMUNICATING WITH PARENTS

Be familiar with communicating with different types or groups of parents. Specific guidelines for communicating with particular groups or types of parents have been identified and discussed throughout the school psychology literature. The rationale for the provision of such guidelines was summarized by Jensen and Potter (1990) as follows: "Parents approach a meeting with school personnel from a variety of perspectives and backgrounds. The psychologist must be sensitive to the unique needs that parents bring to a communication setting and be responsive to those needs" (p. 192).

Suggestions for communicating with specific populations of parents can be found in the following resources:

- Parents new to special education (Flagg-Williams, 1991; Jensen & Potter, 1990; Ormerod & Huebner, 1988; Sattler, 1992; Simpson, 1982)
- Experienced parents (Jensen & Potter, 1990)
- Passive parents (Jensen & Potter, 1990)
- Assertive parents (Jensen & Potter, 1990)
- Angry parents (Jensen & Potter, 1990; Margolis, 1991)

BEST COPY AVAILABLE

- Alienated parents (Calabrese, Miller, & Dooley, 1987)
- Handicapped parents (i.e., parents with disabilities) (Jensen & Potter, 1990)
- Mobile parents (i.e., transient families) (Jensen & Potter, 1990)
- Culturally different and minority parents (Jensen & Potter, 1990; Li & Liu, 1993; Simpson, 1982)
- Non-English-speaking parents (Jensen & Potter, 1990)
- Single-parent families and reconstituted families (Burns & Brassard, 1982; Carlson, 1990; Simpson, 1982)
- Non-custodial parents (Jensen & Potter, 1990)
- Parents at various developmental stages (Pierson & Whaley, 1990)

Other articles have provided guidelines for parents of particular types or groups of children. Such articles include suggestions for parents of:

- College-bound students with learning disabilities (Aune & Johnson, 1992)
- Sexually abused children (Brassard, Tyler, & Kehle, 1983; Hillman & Solek-Tefft, 1988)
- Gifted children (Anderson, 1987; Brown, 1982; Sattler, 1992)
- Children with developmental disabilities (Harris & Fong, 1985)
- Rural children with disabilities (Latham & Burnham, 1985)
- Adolescent drug users (Severson, 1984)
- Children with elective mutism (Lazarus, Gavilo, & Moore, 1983)
- Socially withdrawn children (Sheridan, Kratochwill, & Elliott, 1990)
- Children with severe disabilities (Downing, 1989)
- Visually impaired children (Erchul & Turner, 1987)

In addition to the references listed above which address particular populations of parents, there are several general principles which relate to all school psychologist–parent communications. These principles are as follows:

Treat parents as you would wish to be treated if the situation were reversed! Most of us would expect to be treated courteously and kindly. Appointments should begin on time. Information should be presented candidly yet in an understandable manner. Ample time should be allowed for questions to be asked and adequately answered. Meetings should be held in rooms which allow for privacy and confidentiality of information shared. Interruptions of such meetings should not be allowed except in case of emergency.

In addition, parents should be recognized and treated as individuals. Some parents do not wish to be bothered with attending pre-assessment meetings, post-assessment meetings, and multidisciplinary staffings. Other parents wish to be as active and visible as possible in their children's educational planning and welcome any and all opportunities for involvement. Simpson and Fiedler (1989) on the topic of parental participation in IEP conferences noted that

> while PL 94-142 has effectively promoted an individualized perspective toward all children with disabilities, ironically it has not applied the same emphasis on individualization to parents . . . decisions about the degree of parent involvement in IEP conferences should be made on the basis of individual preferences rather than generalized expectations. (Simpson & Fiedler, 1989, p. 149)

Simpson and Fiedler go on to suggest that parents should be given a choice as to how involved they wish to be in the IEP process and that school personnel should not assume that more parental involvement is either better or worse than less involvement.

School psychologists should make every effort to inform parents of their options. Parents, however, should have the final say in choosing from among the options.

Focus on the interpersonal aspects of school psychologist–parent communication. Treat parents with dignity, respect, honesty, and empathy. Reinforce parents for the efforts they make and for the positive things they do for their children. If parents confide in you, thank them for their trust and their honesty (Sattler, 1992). If parents make special efforts to attend a conference or staffing, acknowledge their efforts. Find positive and unique things about each child you work with and share those observations with the parents. Reassure parents, when appropriate, that they are "good parents." Make every effort to include parents in discussions during staffings just as you might try to "draw out" a reticent guest in your home. Keep in mind how strongly most parents identify with their children. When a negative comment is made about a child, the parents often take it as a personal criticism either of themselves or of their parenting skills.

Help teachers, principals, and other school personnel improve their communication skills with parents. School personnel often report that they were unprepared in their own training to communicate with parents (Fish, 1990; Strickland, 1982). Yet dealing with parents is a big part of the job for those who work with children. Volunteer to address communication skills with parents at a teacher or administrator inservice. Provide opportunities for participants to role-play potentially difficult cases (e.g., defensive parents, feuding parents) and then discuss the role-playing efforts. Provide guidelines for ways in which teachers can organize their conferences such that all of the important information is covered while making sure that time is allowed for parents to share their concerns or ask their questions. Suggest that an advisory group of parents be established in your schools in order to elicit opinions concerning parent–teacher conferences (e.g., length, frequency, structure). If the parents in such an advisory group are a relatively homogenous group and not representative of other parents in the school district, consider conducting a survey of all or of randomly selected parents to obtain more diverse opinions. Perhaps the improvement of parent–teacher conferences could be adopted as a goal of the local parent teacher organization. Also suggest that teachers communicate more often to parents through informal newsletters or notes. Children can be relatively poor "transmitters" of information as to classroom events and activities.

Provide parents with resources. Even if you meet with parents before and after assessing individual children, many parents want more of your time and expertise. Parenting generally is an isolated occupation. Parents are not provided with owners' manuals and the advice received from well-meaning relatives, friends, and strangers usually ranges from the inappropriate to the offensive. To make matters worse, it may take 20, 30, or more years for parents to find out how they did and whether or not they made the right decisions. Most parents are genuinely concerned about their children and want to do what is best for them. School psychologists can reach a large audience of parents through speaking engagements at school functions (e.g., PTA meetings); service organizations (e.g., Rotary, Lions); and more specialized groups (e.g., Parents without Partners). Many of these groups have regularly scheduled meetings and program chairs are often desperate for speakers. Volunteer! If public speaking does not appeal to you, consider offering advice or presenting new ideas to parents through newspaper or newsletter columns. The National Association of School Psychologists newsletter, *Communiqué*, has a feature entitled, "Byline School Psychology," with sample columns you can use or adapt.

School psychologists might also consider developing reading lists for parents who want more information about particular topics (e.g., attention deficit hyperactivity disorder [ADHD], learning disabilities, discipline). There are many such books available to the general public in libraries and/or bookstores. Make it a practice to read through these books on a regular basis to determine which might be most worthy of your recommendation. Such efforts on your part would not only be helpful to parents but also would count towards hours needed for Continuing Professional Development. Sattler (1992) provides a list of "general sources of information for parents of handicapped children and for children" (p. 785–787) although most of the books listed were published prior to 1980. A few more recent references are suggested in the annotated bibliography at the conclusion of this chapter.

Another resource school psychologists can provide for parents is to help in establishing support groups of parents with children with similar difficulties. Parents of students with disabilities may feel as though they are the only ones whose children are experiencing difficulty in school. Schell (1981) noted that with all of the talk about teacher burnout, little attention has been paid to the phenomenon of "parent burnout." Parents of children with disabilities often need support systems desperately. Establishing a school-based group of parents of children with disabilities can meet some of these needs by providing a safe forum to share ideas and information and lessen feelings of isolation and burnout. Speakers can be brought in to address particular areas of interest (e.g., the impact of inclusion on students with disabilities, the use of medication for students with ADHD). School psychologists speaking to such groups can explain in general the types of assessment information we gather and the ways that information is used. Thus, parents will become more knowledgeable about assessment procedures overall prior to subsequent conferences in which their children's performance on specific tasks is discussed. Many parents may be more likely to try intervention strategies which other parents have implemented successfully.

School psychologists can also improve their communication with parents through running parent groups for parents experiencing problems with discipline, parents going through separation or divorce, and so forth. For school psychologists lacking the time, energy, or expertise for such groups, it may be helpful to act as a liaison with a local mental health center or other resource in order to find someone who is willing to provide such a service in the community.

Periodically assess your skills in communicating with parents. A study by Zins and Fairchild (1986) indicated that only 13.3% of a national sample of school psychologists gather accountability data from parents. Yet such data collection is certainly not only possible but desirable. Fairchild (1985) described a system in which parents as well as teachers were asked to complete questionnaires evaluating school psychology interns' skills in assessment and intervention. From a different angle, Wise (1986) provided an instrument designed to help school psychologists assess their own parent conference skills. Her "Self-Evaluation of Parent Conference" form focuses on such areas as the school psychologists' courteousness, openness, honesty, and organization during parent conferences. Medway (1989) summarizes the results of 27 studies examining the effectiveness of parent education programs and groups, by examining whether parents changed their attitudes or behaviors as a result of such training. Results were encouraging and demonstrate ways to assess effectiveness of yet another school psychologist-parent activity. Perhaps somewhat surprisingly, no studies were identified that examined the effectiveness of school psychologists' telephone conversations with parents. Yet as cited earlier, Fish and Massey (1991) found that the largest amount of time (40%) that school psychologists spend in parent communication involved telephone conversations. Certainly research is needed into this much-neglected mode of communication.

SUMMARY

Throughout this chapter, an effort has been made to demonstrate ways in which school psychologists can improve their communications with parents. Reasons were provided as to why improved communication with parents is desirable in terms of helping parents, helping children, and helping the professional image of the school psychologist. Improved communication with parents transcends the various roles and functions of the psychologist in the schools. It is difficult to imagine any professional function of school psychologists that is unrelated (at least indirectly) to working with parents. Assessment of students, for example, involves parental awareness, consent, cooperation, and collaboration while the planning and implementation of intervention strategies involves parental consent, cooperation, collaboration, and active participation.

There are many methods by which school psychologists can go about improving their communications with parents. Such methods include but are not limited to treating parents as you would want to be treated under similar circumstances; focusing on the interpersonal aspects of our communication with parents; helping other school personnel to improve their communication skills with parents; and providing parents with additional resources (e.g., readings, handouts, support groups, and parenting groups).

In order to improve communication skills with parents, it is important to assess realistically the current level of such skills and to identify, document, and measure, in some way, efforts made to improve such skills. Such assessment should be an integral part of one's total professional accountability plan.

Best Practices in Facilitating Services in Urban Settings

Joseph D. Perry
Cleveland Public Schools
and University of Akron

OVERVIEW

In contrast to Jackson's (1990) chapter on urban school psychology in *Best Practices–II*, this review is focused on facilitating services. The focus includes conceptual and practical issues for planning, developing, expanding, and implementing urban school psychology services. A primary rationale is that large urban schools present both opportunities and challenges to providing effective school psychology services that differ from those encountered in other types of school settings. The intent is to emphasize the necessity of developing comprehensive services that meet the unique challenges of serving urban youth within the at-risk ecology of large-city schools.

The general issue of facilitating services is highly relevant in view of recent legislative and professional developments that impact service delivery. For example, the American Psychological Association (APA) has recently developed a task force on an urban initiative as well as task forces on related topics of violence and substance abuse (Cantor, 1993). The urban task force was initiated by the APA president (Cantor) and is directed at the "crises" urban youth experience in adjustment and learning.

A major caveat for facilitating or even conceptualizing the challenges confronting school psychologists in urban settings is that a data-based needs assessment should initially be conducted. Urban schools are complex and vary not only in size of population but also in terms of organizational structure, special education services, demographics, risk factors, and a multiplicity of other variables. Hence, school psychology services should attempt to address the unique needs of a specific urban setting. The content of a needs assessment is reflected by the issues reviewed in the basic considerations section and will be described later in the practice guidelines. Facilitating program development for services needed in an urban school system often requires knowledge bases that the typical school psychologist lacks such as violence prevention and Comer's Yale Child Study Model (Cantor, 1993). Hence, facilitating services in urban settings is a complex process.

Best practice guidelines are provided concerning multiple topics such as facilitating the following: leadership, needs assessment, public relations, grant-funded programs, and alternative services. The last issue of alternative services is especially relevant for urban settings. There are typically special projects and multiple departments in urban schools that could benefit from involvement of school psychology services. Types of alternative services reviewed include the School Development Program (SDP); an intervention project in Chapter I programs; an intervention program for expelled students; and crisis/violence intervention services. The more specific nuances for implementation will be reviewed in the best practices section to provide the reader with practical examples for promoting services.

BASIC CONSIDERATIONS

Recent publications have pointed out the failure of large urban schools to address the needs of urban student populations (e.g., Bracey, 1993; Bullard & Taylor, 1993; Cantor, 1993). Indeed, youth living in urban settings have been found to present similar stress reactions to those living in "war zones" according to cross-cultural research findings conducted by Garbarino, Dubrow, Kostelny, and Pardo (1992). However, Cantor (1993) states "the science and profession of psychology, with the broadest understanding of human behavior of any science and profession, has not made a unified, concerted effort to address the urban crisis" (p. 5). To illustrate the uniqueness of the needs of inner city youth, a brief review of the characteristics of urban schools and the problems encountered are provided in this section. Other issues that have impact for facilitating services in urban public school settings are also reviewed.

Demographics

The 1990 census reported that about one-third of the U.S. population resides in the 488 cities with populations above 50,000. The demographics of cities have been changing during the past 25 years. Urban public school populations have been reduced due to families of all races with higher socioeconomic levels moving to the suburbs and increased enrollments of private and parochial schools (Bracey, 1993; Zero Population Growth, 1993). School districts of the nation's 25 largest cities now have student populations composed of cultural, ethnic, racial, and linguistic groups (Ponterrotto, 1990) leaving whites in the minority. The Greater Washington Research Center (1993) found that half of the nation's 488 largest cities also have poverty rates exceeding the national average of 13.14%. The 25 largest cities with the highest poverty rates also had populations that were composed of over half minorities. Typically, urban school populations have poverty rates and minority representations higher than the total city population in which they are located. For example, Jordan (1993) pointed out that Atlanta's general population is 67% African American but 92% of the public school's enrollment is composed of African Americans. Similarly, the Cleveland Public School's population has a poverty rate of over 70% as defined by school lunch status and is composed of about 76% minorities.

It is not just the concentration of minorities and poverty in urban schools that creates risks for youth, but rather an ecology characterized by high crime, gang involvement, single-parent families, unemployment, family mobility, and population density (Garbarino et al., 1992; Hammond & Yung, 1993). Moreover, as Hammond and Yung point out, current explanations are not adequate because many impoverished African American youth in urban settings do not present maladjustment.

Educational Deficits, Stress, and Violence

There is considerable evidence indicating that urban public school populations are increasingly at risk for negative sequelae to multiple stressors in all areas of development. For example, it is estimated that about 20% of first-grade students in large urban settings need remediation to master the initial reading curriculum (Madden, Slavin, Karweit, Dolan, & Wasik, 1991). The school dropout rate in large urban settings is reported to range from about 41% to 50% (Bullard & Taylor, 1993; Council of Great City Schools, 1987). Educational deficits for those who stay in school were also reported by a recent nationwide study conducted for the U.S. Department of Education by the Abt Associates (1993). Schools with demographics similar to large urban settings (e.g., low socioeconomic status [SES] as defined by at least 75% of students qualifying for free and reduced price lunch) had only 15% to 32% of students attaining a grade-point average (GPA) of 3.0 or higher while 35% to 47% of students in low-poverty schools attained this GPA. Moreover, students from high-poverty schools with the 3.0 or higher GPA scored lower on standardized tests in reading and math than students from low-poverty schools with a 2.0 GPA. Educational deficits may be related to other problems such as multiple stresses and especially violence which according to recent reports has dramatically increased for urban youth.

A recent nationwide study by Zero Population Growth (1993) reported that youth in the 195 largest U.S. cities experienced more stress than those in other geographical locations (i.e., 493 counties and 239 metropolitan areas). It was generally found that higher population density was associated with greater stress for children based on an index of 70 indicators such as crime, health care, educational outcomes, and community economics. Out of a top positive score of 100, the 8 worst cities in order of stress for children and their scores were Newark (27.4), Gary (29.1), Cleveland (29.4), Chicago (29.6), Detroit (30.5), Miami (32.5), Los Angeles (33.3) and Houston (33.3). This is in contrast to average ratings of about 65 for counties and metropolitan areas.

Garbarino et al. (1992) reported that violence is the major stress for urban youth. Hammond and Yung (1993) pointed out that homicide is now the leading cause of death for African American male adolescents with a 55% increase between 1985 and 1990. Sample statistics cited by Hammond and Yung include: (a) the majority of urban youth have witnessed stabbings and shootings and one-third have directly observed a homicide; (b) death rates are 5 times higher for inner-city youth than those in other settings; (c) urban African American male adolescents are most likely to be both perpetrators and victims of violence; and (d) 20% of urban youth are threatened with a gun and 12% have gunfire directed at them. Garbarino et al. (1992) reported that violence for urban youth is particularly stressful because the perpetrators are often persons familiar to the victims. Although Hammond and Yung (1993) reported a lack of adequate explanations for the increasing rate of violence, they also noted recent hypotheses including (a) racism and poverty with hostile responses due to resentment, hopelessness, and self-hatred; (b) drug and gang involvement with such cultural values as high status for violent offenders; (c) inner-city residence with family dysfunction, crowding, and community disorganization.

There are many other indicators of negative developmental sequelae and risks for urban youth that could impair school performance. These include increased rates of drug and alcohol abuse, adolescent pregnancy, gang involvement, suicide behavior, and sexually transmitted diseases. A recent text edited by Gaw (1993) indicated that the prevalence and nature of mental health problems varies for different cultures and types of residence with implications for differentiated interventions. Because of the stress and violence already prevalent in their lives, urban youth could be expected to present a high prevalence of adjustment problems to loss from death experiences and parent separation. School psychologists working in urban schools are in an opportune position to address these psychosocial factors as a foundation for facilitating psychological services.

Special Education Placements

Jackson (1990) noted that in urban schools "there is continuing confrontation over who needs and who does not need special education" (p. 759). A salient issue is the recent finding that a disproportionate number of students from minority backgrounds are placed in special education. The *Fourteenth Annual Report to Congress* (U.S. Department of Education, 1992) recently summarized the findings of a federally sponsored study on this topic entitled the National Longitudinal Transition Study of Special Education Students (NLTS). This study provided a demographic profile of a nationally representative sample of special education students 13 to 21 years of age. The findings were more definitive than previous literature such as the National Academy of Science Report in the 1970s and generally indicated that, in comparison to the general population, youth with disabilities were disproportionately male, African American, and from single-parent families with a low SES similar to that of most large urban school populations.

More specific findings regarding race indicated that African American youth were the most disproportionate of any racial group in total special education placements. African American students represented 24% of all special education students but only 12% of the general population studied. Hispanic students were found to be underrepresented (i.e., 8% with disabilities and 13% in the general population) as were white students (i.e., 65 and 70% respectively). African American youth were found to be most disproportionately represented in the disabilities of mental retardation (31%), speech and language impairments (28%), visual impairments (25.9%), and serious emotional disturbance (25%) with less in the high-incidence specific learning disability category (21.6%). The major concern is that African American students are disproportionately identified for special education and other remedial programs for students with "low ability" rather than the less stigmatizing specific learning disability program (Madden et al., 1991; Special Education Committee for the Council of Great City Schools, 1988). The NLTS report did include interpretive hypotheses for the disproportionate special education placement of African American students which could provide urban school psychologists with direction for services to address this issue.

The explanations regarding biased assessments and referral processes have been most frequently reviewed in the past and nondiscriminatory assessment as well as referral procedures continue to have relevance in addressing this issue. However, the increased disability prevalence for minority students due to low SES and early biological risks has not been typically addressed relevant to this issue. The SES explanation in relation to the overrepresentation of black students in special education appears to be supported by the NLTS data since 57% of the African American special education population were from households with incomes below $12,000.

The NLTS explanations regarding the higher prevalence of disabilities for low-SES minority students due to early biological risks may be especially salient for urban school psychologists' understanding of this issue. This was supported by Crosby (1993) who stated that "in major urban areas, it is estimated that one child in 15 has some congenital problem that can impair his or her behavior and learning" (p. 604). Crosby and the NLTS study cited such risks as poor prenatal care, low birth-weight babies, drug-damaged babies, head injuries, and poor health care as occurring more frequently in low-SES minority students residing in urban settings.

When these special education placement statistics are combined with the urban demographic and risk data reviewed earlier, it might be expected that urban public school populations would have disproportionately high special education placements. However, the limited evidence available does not support this projection. The Council of Great City Schools (1988) indicated that about 10% of large urban school populations based on Average Daily Membership (ADM) are placed in special education, a percentage similar to the national average. This possible disproportionality by type of disability and general decreased identification of total disabilities relative to risks for urban school populations may be associated with service delivery issues not typically considered such as the following:

- *Funding of Services.* The number of school psychologists and special services funded by state departments of education are typically based on ADM rather than need as in other countries such as Sweden (Bracey, 1993). The ADM in urban schools does not account for the number of students actually registered in comparison to non-urban schools due to relatively high absenteeism.
- *Time-Delays.* The time required by the tasks inherent in the process of identifying students for special education may be greater in urban than non-urban schools due to various issues (e.g., locating students with high absenteeism; locating parents with frequent address changes and limited phone access; and conducting nondiscriminatory assess-

ments beyond the typical multifactored evaluation).

- *Referral Issues.* While referrals of urban students may be disproportionately high, the caseload capacity of the school psychologists employed probably results in only those with the most severe educational impairment receiving evaluation. This, in turn, may result in identification of a possibly higher prevalence of mentally retarded but not the higher prevalence that may also exist of the less severe specific learning disabled (SLD).

These service-delivery issues extend beyond traditional "gatekeeper" concerns. Clearly, the rates of placements by race and type of disability often have relevance for legal cases related to nondiscriminatory assessment/placement in desegregated urban schools.

Service Guidelines and Resources

Recent revisions to professional and ethical guidelines published by the National Association of School Psychologists (NASP) and the American Psychological Association (APA) have applications for facilitating services to urban settings. The APA *Guidelines for Psychological Practice with Ethnic, Linguistic, and Culturally Diverse Populations* (APA, 1991) generally require that psychologists have a "very thorough understanding" of how culture may affect the provision of services. The NASP position statement, *At Risk Students and Excellence in Education: The Need for Educational Restructuring* (1992), provides implications for school psychologists to broaden services for students who present risks typical of urban youth. The 1992 revisions to the NASP and APA ethical principles require that school psychologists attempt to identify the degree that services apply to youth when considering SES, race, ethnicity, and other factors. These generally indicate the need for expanded training and supervision in order to improve providers' competencies in serving students of diverse ethnic and cultural backgrounds.

Goals of Services

While not typically addressed, a conceptual foundation for providing support services to inner city youth relevant to the pessimism and apathy that can permeate an urban school system (i.e., "a nothing works attitude") was reviewed by Garbarino et al. (1992). It was recommended that early intervention should generally be directed at promoting children's ability to cope by preventing a "build-up" of stressors. This was based on studies illustrating that it is multiple stressors which predict negative developmental outcomes rather than a single stressor. Zigler (1990) stated that "no amount of counseling, early childhood curricula, or home visits will take the place of jobs that provide decent incomes, affordable housing, appropriate health care, optimal family configurations, or integrated neighborhoods where children encounter positive role models" (p. xiii).

Thus, a conceptual foundation for facilitating school psychology services in urban settings could be viewed as helping children cope and preventing an accumulation of risks. For example, reducing academic failure and adjustment problems at school may reduce only one stress but this may help urban children avoid a total breakdown in adjustment. There is a particular need for school psychologists to address the impact of ecological and demographic variables (e.g., SES, stressors, and race) in outcome studies when evaluating services.

Summary

Many other basic considerations for facilitating services to meet the unique needs or urban youth could not be reviewed due to the space constraints of this chapter. Examples include such considerations as children's physical health, family issues, child abuse/neglect, mental disorder prevalence, and influences of various cultures on service delivery. Issues selected for emphasis in this section and their implications for facilitating services are provided in the best practices section.

BEST PRACTICES

Few conceptual and empirical foundations based on validated best practices for facilitating services in urban schools exist. Hence, this section offers suggestions based on recent experience in expanding school psychology services in an urban setting. The intent is to provide practical applications to address the organizational issues and actual nuances likely to be encountered when attempting to implement comprehensive school psychology services in a large-city school district.

General Implications of Basic Considerations

Influence of culture and disadvantage. Most urban school populations are now composed of cultural, racial, ethnic, and language minority students and thus school psychologists need a comprehensive understanding of how these factors influence learning and adjustment. Familiarity with influences of deprivation associated with low SES is also critical. Urban school psychologists should routinely indicate the degree that culture and deprivation influence a child's school performance relevant to nondiscriminatory assessment and culturally sensitive interventions. General implications include staff training on these topics and recruitment of culturally diverse school psychologists.

Prevention of school failure. About 20% of students lack the school-entry competencies needed for mastering the first-grade curriculum and as many as 50% do not graduate. School psychologists could assist schools in early academic intervention and prevention programs as well as drop-out prevention programs. "Success for All" (Madden et al., 1991) is a model program that could be applied for this need.

Services for stress and violence. Considering the evidence presented concerning the heightened stress and violence experienced by urban youth, school psychologists should target these areas for services.

Special education services. There is continuing confusion regarding the prevalence of urban students with disabilities and the need for special education services in urban settings. In view of the updated data and considerations reviewed, increased school psychology and special education services are needed. The referral process in urban versus non-urban schools may differ substantially in the determination of suspected disabilities. Rather than just increasing the number of students identified for special education, schools could provide a broader range of special services and improved programs within regular education. Early intervention and prevention programs are also needed. Consistent with the current trend of inclusion, an increased number of urban students with disabilities could be provided with services while attending regular education. However, students' needs should be identified.

Public Law 101-476 (Individuals with Disabilities Education Act, IDEA) targeted students with disabilities from minority backgrounds for improved services. One approach to addressing the needs of urban students with disabilities would be to expand the related service of direct counseling and mental health interventions by school psychologists. This could be directed at reducing the increased stresses that urban students with disabilities are likely to encounter which may impair their school performance.

Mental health services. Increased mental health interventions could be delivered by coordinating with special projects that often exist in urban schools and community agencies. Sample services that are most needed include crisis intervention, school team intervention policy for discipline, and prevention programs.

New guidelines and resources. Recently published professional developments and resources have particular applications for facilitating services in urban schools. New ethical and professional standards are more explicit in meeting the needs of diverse minority populations. School psychologists are in need of continuing education on these topics. The reader is referred to the Annotated Bibliography at the end of this chapter as a basic starting point.

Leadership Issues

An advantage for facilitating services in urban versus non-urban schools is the greater likelihood that supervision would be provided by an administrator who is a school psychologist. This is the result of the relatively greater number of school psychologists employed in urban settings with the need for supervision of this separate service. However, Talley (1990) pointed out that various administrative structures within the school's bureaucracy influence the effectiveness of leadership for facilitating psychological services. Moreover, there is a lack of data regarding the efficacy of various theoretical models for supervision (Iverson & Iverson, 1993). A recent review of the literature on this topic by Iverson and Iverson indicated the following inadequacies regarding supervision in school psychology: (a) only 30% of practitioners were supervised and most of this was on an "as needed basis" and (b) the majority of supervision was provided by nonpsychologists. Considering the complexity of supervision and these limitations, the best-practice guidelines on this topic are restricted to suggestions with explanations concerning applications for facilitating services in urban settings.

School district organization. If at all possible, school psychology services should be organized as a separate department in the school district with the director or supervisor reporting to higher administration such as an assistant superintendent. This would enable comprehensive services to both special and regular education students to be coordinated with the multiple school departments and community agencies needed for effective delivery of services. However, this is not typical, and the second most desirable organizational structure is placement of school psychology within a pupil personnel or student services department. While this alignment may help in coordination with other student services and still enable school psychologists to work in programs serving both regular and special education students, there is the possibility that leadership will be provided by an administrator without school psychology competencies. A less desirable organizational structure for facilitating services is placement in a special education department. This may impair the expansion of services beyond the narrow gatekeeper function for special education. The least desirable administrative organization is building-based where services are decentralized and supervision is provided by school principals. This has obvious limitations such as staff being assigned unrelated duties with possible violations of professional standards.

It is critical that higher administration be educated about the professional standards for school psychologists and the need for a school psychologist to provide leadership for this service. Recent urban-school reform trends that include such decentralized issues as site-based management (Bullard & Taylor,

1993) should not apply to the needs for effectively administering school psychologists (Bard & Hardy, 1991). The optimal time to develop a plan for expanding services is during the employment process of a supervisor of school psychologists: This is when the higher administration may be most available and receptive to suggestions for administrative structure reorganization based on a plan for facilitating optimal services applications.

Staff organization. A critical component of supervision for facilitating services is the manner in which a large urban staff is organized for assignment and service delivery. The relatively large number of school psychologists in addition to multiple types of service opportunities in large urban settings make assignment of staff a challenging task.

Guidelines for assigning the school psychology staff in a manner that facilitates services include the following:

1. Major criteria are the competencies of staff for the specific assignments. For example, those with training and experience in serving preschool students would be assigned to this service.

2. Consumers of services should be involved in decision making regarding assignments. For example, administrators of special projects may wish to interview staff with competencies and interest for that project.

3. While school psychologists' salaries may be funded by special projects, the administrators of these projects should be informed of the need for continued supervision by a psychologist administrator. A helpful approach is to fund staff only for part-time assignment to new programs with the remainder of time on regular assignment. This has several advantages such as enabling staff to maintain competencies for traditional roles while providing new services.

A strategy for planning new services is organizing staff committees. This involves encouraging school psychologists with special competencies to serve as co-chairs of committees and then requesting that the remainder of staff serve on committees. A critical issue is identifying the topics or areas that could facilitate services for the committees to consider. Committees for a large school-psychology staff have several advantages such as (a) staff training for advanced skills, (b) involvement of staff in decision making, (c) assistance for the administration in planning new services, and (d) peer support for developing the staffing competencies. The following are sample committees with possible applications for facilitating services in urban settings:

1. *Research and Grants.* This committee could help design and implement research studies and grants that could address facilitating services.

2. *Staff Development.* It is critical to gain the staff's input for providing staff development. This helps school psychologists gain the competencies needed for facilitating services.

3. *Crisis Intervention.* The need for ongoing refinement in policies, guidelines, and implementation of this challenging service could be addressed by this committee. While all staff in urban settings are expected to have competence in crisis intervention, committee leaders and members could provide support to staff when needed.

4. *Multicultural and Bilingual Services.* This committee could help plan and implement services and staff training to address the needs of minority and bilingual students.

Many other types of committees could be helpful for staff organization beyond those directly relevant to facilitating new services (e.g., newsletters, intervention handouts, and best practices in intervention and assessment). Ad hoc committees could also be formed as needed for short-term needs or opportunities relevant to facilitating services.

Another critical leadership task is the recruitment and employment of school psychologists for urban schools. Beyond recruiting cultural and ethnic minority staff, several other criteria that could help facilitate services include professional experience working with urban youth, competence for specific alternative school services, and other general qualities of positive employees.

Needs Assessment and Planning

It has already been stated in this chapter that needs assessment is the critical initial step for facilitating services in urban settings. It is within the competence of school psychology to facilitate not only psychological services but also general education programs and other services. A comprehensive assessment would be focused on the needs of students plus the existence of multiple risks and support systems. Considering the sample data reviewed earlier, the needs of students should reflect an index of problems, such as the prevalence of special education disabilities, mental health disorders, school failure, academic functioning, cognitive abilities, physical health, death/suicides, violent behavior, discipline/juvenile violations, school attendance/dropouts, drug abuse, and sex problems/pregnancies. Risk factors include stresses and other ecological characteristics that may increase the problems youth encounter. Support systems are protective factors that may reduce or prevent the problems youth experience.

To interpret the degree of need for services, data from national, state, and local metropolitan areas should be compared to that of the urban school district being served. Staffing by ADM could also be compared to other school settings, especially the metropolitan area or suburbs of the city. The data may resemble the information presented in the basic considerations section indicating greater problems and risks but less support for the urban population. It may also reveal that more school psychologists are employed per ADM in the metropolitan area, especially in suburbs with high SES, than in the city.

The following methods could be used in conducting a needs assessment that addresses the factors just described.

Kindergarten screening. Screening kindergarten students could provide indicators of the students' school-entry cognitive and social skills. Parents should be given an opportunity to have input regarding support systems, risk factors, social/behavior ratings, and health background. This information could serve as a basis to request general education support based on needs and as background for grant applications.

Demographic data. Total school district and city data could be requested from a research department such as exists in many large-city schools. Data regarding mental and physical health as well as education could be requested from local mental health boards, pediatric hospitals, local census offices, and state departments of education.

Surveys. Teachers, administrators, school psychologists, and other school personnel could be surveyed regarding relevant issues and the perceived need for psychological services. Parental input could best be gained through a telephone survey.

Annual reports. The services provided by school psychologists are typically summarized in an annual report. This report should include a comprehensive summary of services and aspects of the needs assessment data. Implications for facilitating services should be written in the report.

Application of the needs assessment for alternative and improved general services by school psychologists should be provided in written reports. For example, if stresses and risks are found to influence educational outcomes, implications for psychological services to address these problems should be specified. General implications for general school programs could also be provided.

It should be noted there may be resistance to a needs assessment due to concerns that this could be stigmatizing to the schools and that implications would be costly. One response is that the data would be used formatively to plan services and seek funding as well as to provide explanations for the existing stigmatizing information often cited about large urban schools. Helping the schools to be sensitive to students' needs and developing responses to meet those needs were recommended as major tasks for support services in urban settings (Garbarino et al., 1992).

Public Relations for Promoting Services

Urban schools have complex political and bureaucratic structures with various administrative and other units influencing system-wide change. To facilitate services, supervisors and school psychologists should study all school departments and convey an interest in applying psychological services to the mission and needs of these departments. This is especially possible when urban school districts form task forces to plan reform. School psychologists and supervisors should volunteer to serve on these groups. This must be conducted in a politically sensitive manner with recognition of both the explicit and implicit values of various school departments and disciplines.

There are many other ways of gaining visibility and seeking to be actively involved in as many levels of the school and community as possible. A brief summary of some examples include the following:

- *Staff Development.* Prepare a list of staff development topics that school psychologists could provide and distribute it to all schools, administrative units, parent groups, and community agencies. Some salient topics are discipline, violence prevention, and crisis intervention.
- *Newsletters and Intervention Handouts.* A staff committee and the supervisors could write these and distribute them on a district-wide basis to help school staff address students' needs.
- *Parent Support Groups.* Parents who demonstrate leadership abilities could be organized into various support groups (e.g., types of disabilities). School psychologists could serve these groups by providing parent education regarding the special needs of these students and interventions that could be provided at home. Parent leaders could be involved as mentors, and other parents in need of assistance could be referred to them.
- *Media Communication.* Supervisors and staff could work in cooperation with the school's community relations department to provide written reports and speeches when needed on special topics or situations that may arise.
- *Community Agency Boards.* Sending letters to relevant community agencies to express interest in serving on advisory and executive boards promotes involvement and knowledge of community services.
- *Annual Reports.* These reports could be written in a format that explains the nature of services provided and future needs. The annual report should be distributed to all relevant school personnel and agencies.

Grant-Funded Services

Grants can be sought to implement innovative programs and research. The needs assessment data described earlier could be used as the justification for funding typically required by grant applications. Here is an area where urban schools may have an advantage because of the many characteristics present that are enablers for seeking grants. These include: (a) a large, economically disadvantaged population; (b) availability of grant-funding sources such as large businesses; (c) community agencies for multidisciplinary approaches; and (d) the presence of universities for assistance in research.

Current trends or themes targeted by grant-funding sources are highly relevant to the needs of urban schools and school psychology services. Examples are: (a) special needs of students with disabilities from minority backgrounds; (b) case-management mental health interventions; (c) multi-agency services for students with emotional and behavioral disabilities; (d) improved services for preschool students with disabilities; (e) violence- and drug-prevention programs; and (f) recruitment of minorities in school psychology and development of culturally sensitive interventions. There are multiple types of grant-funding sources relevant to school psychology services including local philanthropists and state and federal agencies in not only education but also mental health and medicine.

Working collaboratively with multiple school departments and community agencies to seek grants increases the likelihood of success. School psychology services could be the major focus in some grants and secondary or supportive for other grants. School psychologists could provide not only assessment and data-gathering for grant-funded programs but also direct and indirect interventions.

Alternative Services

The term *alternative services* has recently been used to describe school psychology functions beyond those provided for special education students with disabilities. The NASP publication on this topic (Graden, Zins, & Curtis, 1988) provided an extensive review of multiple applications but not to urban settings specifically. In urban settings, there are typically many students with risks and needs beyond the criteria for special education who require more immediate psychological intervention services. Hence, a general theme of alternative school-psychology services would be providing direct and indirect intervention to minimize students' adjustment problems that may impair learning. In keeping with the school district's goals and programs, these could be conceptualized as failure-prevention services rather than special education identification and placement services. Examples of prevention, intervention, and other alternative school psychology services are briefly described below.

School Development Program (SDP). This primary and secondary prevention program has also been described as the Comer Yale Child Study Model and is intended to promote the school adjustment of urban minority students from disadvantaged backgrounds (Haynes & Comer, 1990). In the SDP, a school psychologist works with a school team that includes teachers and parents and is chaired by the principal. This team reviews the school's climate in terms of plans and activities as they relate to the prevention of students' behavior problems.

An Intervention Assistance Team (IAT) format addresses individual problems experienced by students and school staff. Parent involvement in all aspects including general curriculum planning and individual teams is emphasized. A major goal is to reduce the discontinuity between home and school which Jackson (1990) reported to be present for urban youth. Positive outcomes have been reported by Haynes and Comer concerning the general school climate as well as student criteria in the areas of self-concept, behavior, and academic achievement.

Crisis intervention. School psychologists could help urban schools develop policies and procedures for this secondary and tertiary prevention service which involves multiple school personnel and community agencies. Principals should have primary responsibility for the crisis referral in addition to notifying higher administration, parents, and involved school departments. Most urban schools have security departments that work with the police and these personnel should have responsibility for managing students experiencing crises. Local mental health boards may provide outreach programs and crisis services that could be involved when follow-up beyond school is needed.

School psychologists provide initial consultation to the principal and school crisis team. Direct intervention for students when life-threatening behavior is present should be provided in compliance with ethical and due-process principles. Consultation with parents and community agency staff in addition to staff development for school personnel are important roles for school psychologists. A major service is follow-up assessment and planning when the student returns to school after a crisis.

Violence prevention/intervention. Hammond and Yung (1993) reviewed recent school-based violence-prevention programs for African American inner-city youth. These apply cognitive-behavioral approaches to reduce violence by teaching prosocial behavior such as social problem solving, modeling, and group training of social skills. School psychologists are familiar with these types of interventions and continuing education could provide applications to violence prevention. The role of the school psychologist would be similar to that in crisis intervention, namely as consultant plus provider of staff development support and parent education services that promote prevention. Students who have experienced violence could be included in follow-up intervention and prevention services by school psychologists.

Alternative to expulsion program. Due to the problems associated with violence (reported earlier), the rates of expulsions as well as suspensions are typically high in urban schools. Absenteeism and eventual dropping out of school are related problems. A major need that school psychologists could address is helping the schools meet recent legal requirements for expulsions and suspension relevant to students with disabilities or suspected disabilities.

Recent pilot programs have been implemented in urban schools to provide an alternative to expulsion. School psychologists could assist in developing an educational and support program that could be housed in a separate facility or in a section of a school. Rather than being expelled, students along with their parents could elect to attend this program. Students would be provided with continuing education in addition to support services by school psychologists funded to serve in this program. The role of the school psychologist would involve not only assessment to rule out disabilities and mental health problems but also the provision of direct and indirect interventions for students.

Compensatory education. Recent developments in compensatory education programs funded by Chapter I have included decentralization to "school-wide" projects with school-building teams designing remedial education programs. Urban schools typically have extensive Chapter I programs due to disadvantaged school populations. Decision making regarding the budget for these programs is typically provided by a school building team. School psychologists could provide assistance to this team by designing failure prevention programs that include funding of psychological services.

The general theme of psychological services for these programs would be interventions for students with adjustment and learning problems that may impair their classroom performance. Sample services include: (a) screening students to identify risks; (b) helping school teams write individual intervention plans; (c) consulting with and educating parents about interventions that could be applied at home; (d) consulting with teachers and visiting classrooms to assist teachers in implementing intervention plans; and (e) providing direct individual and group interventions for students with adjustment problems. An additional need that school psychologists could help the school-wide project address is developing outcome indicators beyond standardized assessment as recently recommended for Chapter I. This could include curriculum-based measures and assessment of students' adjustment.

Alternative discipline programs. School psychologists could offer services to school departments responsible for developing discipline policies and procedures. Many school districts have abolished corporal punishment and are in need of alternatives for administrators and classroom teachers. School psychologists could help by applying recent developments in cognitive-behavioral approaches to discipline programs. The content of this program could include such information as the following: (a) multiple theoretical and procedural models of discipline; (b) applications of behavioral assessment for prescriptive discipline techniques; (c) teaching positive social skills to prevent discipline problems; (d) cultural influences on behavior and culturally sensitive discipline techniques; and (e) applications for students with disabilities and special needs.

Beyond developing written plans, school psychologists could provide assistance in implementation through staff development and parent education. School psychologists could also encourage teachers to apply the alternative discipline techniques in IAT services.

Case-management mental health services. Case management, a model currently being implemented by many community mental health agencies, emphasizes coordination of services for an individual rather than provision of services in isolation. To provide a school liaison for this service delivery model, school psychology leadership could serve on children's mental health planning boards as the school district's representative. Funding for school psychologists to work as part of the mental health team could come from special projects related to this approach. This interagency approach has been recommended by PL 101–476 as a way to improve services for students with serious emotional disturbances (SED).

Many other types of alternative services could be provided by school psychologists in urban settings beyond those briefly described here. Written summaries could delineate how school psychology services are relevant to the missions and services provided by other professionals in programs administered by multiple school departments and/or community agencies. Examples include adult education, career education, health services, staff development, and various community agencies.

SUMMARY

The major approach recommended for facilitating services was adapting school psychology functions to meet the needs of inner city youth and urban schools. Considering the severity and nature of the problems experienced by the students as supported by the data briefly reviewed, this task should be approached with a spirit of "aggressive opportunism." That is, school psychologists cannot wait for the school administration or other entities to seek their services, but rather should seek opportunities to apply their services to students' needs.

Two general implications for services include nondiscriminatory assessment and culturally sensitive interventions. While knowledge concerning the influence of culture is at a rudimentary level, assessment and interventions could be directed at the major risks confronting urban youth (i.e., stress and violence). However, this is challenging because, as Garbarino et al. (1992) observed, "the run down, overburdened inner city school is locked into a rigid curriculum that makes it difficult to meet the special psychological agenda imposed by trauma" (p. 229).

Many of the needs for providing effective services implicit in this review may not be consistent with current "bandwagons." For example, such trends as decentralization, reduction of special education by inclusion, and privatization may not be as applicable to facilitating services in urban settings as compared to non-urban schools. This is especially relevant if service delivery and educational reform are driven by needs.

The demographics and risks of urban schools are projected to be increasingly applicable to the general public school population across the nation (e.g., the majority of the national school population will be comprised of minority students early in the next century). Hence, initiatives to improve services in the cities may prove to have more generalized relevance in the future. It is suggested that NASP develop an urban task force similar to APA but with emphasis on school psychology services. It is hoped that this chapter will help stimulate this development by sensitizing school psychologists to the needs of urban youth and implications for expanded services.

ANNOTATED BIBLIOGRAPHY

Bullard, P., & Taylor, B. O. (1993). *Making school reform happen.* Boston: Allyn and Bacon.
This textbook is recommended for school psychologists working in urban settings in order to gain a comprehensive knowledge of urban school reform issues. School psychologists could plan to adapt services for involvement in the school reform programs. Especially relevant are new approaches to remediation in regular education.

Garbarino, J., Dubrow, N., Kostelny, K., & Pardo, C. (1992). *Children in danger: Coping with the consequences of community violence.* San Francisco: Jossey-Bass.
This textbook provides conceptual and empirical foundations for understanding the needs of urban youth as well as facilitating services. The early intervention program is especially relevant for developing school psychology services to address the stressors experienced by urban youth during preschool and the early elementary grade levels.

Gaw, A. C. (Ed.). (1993). *Culture, ethnicity, and mental illness.* Washington, DC: American Psychiatric Press.
Considering that new ethical guidelines require psychologists to have knowledge of how culture may impact services, this textbook is an excellent resource. Multiple authors who have expertise for working with various cultural and ethnic groups review mental health needs relevant to serving the different populations.

Hammond, W. R. (1991). *Dealing with anger: Givin' it, takin' it, workin' it out.* Champaign, IL: Research Press.
This school-based intervention program includes structured cognitive-behavioral techniques and videotaped modeling for aggression replacement training with adolescents. This approach emphasizes culturally sensitive content and can be applied to youth who are either perpetrators or victims of violence.

Hammond, W. R., & Yung, B. (1991). Preventing violence in at-risk African-American youth. *Journal of Healthcare for the Poor and Underserved, 2,* 359–373.
This article provides a model outcome study that is not typically available regarding school-based interventions for reducing aggressive behavior in urban adolescents. It was found that the treatment group evidenced significantly less indicators of aggression than a control group.

Best Practices in Facilitating Services in Rural Settings

Susan Jacob-Timm
Central Michigan University

OVERVIEW

Many Americans hold idealized images of rural America — images shaped by television, movies, and vacation excursions into the countryside. Country life is seen as "the good life," characterized by fresh air and scenic beauty, tightly-knit families, close ties with neighbors, freedom from crime, and freedom from the "constraints, pressures, and fast paced life of the cities" (Hobbs, 1992, p. 21). As Hobbs has noted, however, these idealized images "tend to be at substantial variance with current facts concerning rural America and its communities" (p. 21). Research comparing metropolitan and nonmetropolitan areas shows substantially higher rates of poverty in nonmetropolitan areas, and an increasing number of rural families in poverty (Hobbs, 1992). Studies show that a disproportionately high number of children in rural areas is at risk for school failure and mental health problems (Helge, 1990). Furthermore, most unserved or underserved children with disabilities live in rural areas (Helge, 1985).

There is currently a nationwide shortage of school psychologists, with shortages being most acute in rural areas (Fagan, 1988). Unfortunately, rural communities also often lack adequate numbers of nonschool health and mental health professionals to meet the needs of rural children and their families. One purpose of this chapter is to describe the benefits and special challenges associated with rural school psychology. It is hoped that this will prompt students-in-training and practitioners to consider future employment in rural schools. As Hughes and Fagan observed, "because a large number of handicapped rural children are not receiving the education and mental health services to which they are entitled, professional school psychology bears an ethical and moral responsibility to increase the availability of quality special education and mental health services to the children of rural America" (1985, p. 400).

A second purpose of this chapter is to provide an overview of "best practices" in the delivery of school psychological services in small, rural schools, particularly those located in sparsely populated and remote communities. As discussed later in the chapter, there is great diversity among rural communities and schools. Consequently, the goal here is to provide information and ideas that will encourage rural practitioners to formulate new approaches and solutions appropriate to each unique setting.

BASIC CONSIDERATIONS

This portion of the chapter explores the characteristics of rural communities, families, and schools, and the special benefits and challenges of rural school psychology. It is important to note that there is no widely accepted definition of the term "rural." The distinction between "rural" and "urban" have blurred with the rapid growth of urban sprawl on the periphery of major cities (Hobbs, 1992). For the purposes of this chapter, "rural schools" are those located in communities outside of a Standard Metropolitan Statistical Area, distant/remote from a large city, and in counties where the population density is low (see National Rural and Small Schools Consortium, 1986, for a more detailed discussion).

Rural Communities

As Helge (1985) has suggested, effective practice of rural school psychology is based on knowledge of the special characteristics of rural communities and the unique setting in which the practitioner serves. Rural communities tend to differ widely from one another. Rural New England is very different from rural Iowa, and both are quite different from rural Texas, Alaska, Alabama, Colorado, or West Virginia. Each rural community is shaped by its particular geography, its economic base, and the ethnic and religious makeup of community members (Hobbs, 1992).

Despite their diversity, rural communities often share some common characteristics. In 1988, the average per capita income in rural counties was $12,657.00, only 71% of the urban average (U.S. Bureau of the Census, 1991). Research comparing metropolitan and nonmetropolitan areas has found more unemployment, underemployment, and lower-paying

BEST COPY AVAILABLE

jobs in nonmetropolitan areas. Rural communities historically have depended on natural resource-based sources of livelihood such as agriculture, mining, timber, or fishing. In some areas of the country these industries have declined or disappeared. Although some rural areas now have manufacturing or tourism as part of their economic base, rural communities typically lack the economic diversity of metropolitan areas. Because of this lack, rural areas are vulnerable to periods of economic instability and downturn. Rural communities today often must cope with economic uncertainty and instability, or chronic poverty (Hobbs, 1992).

Most rural communities have undergone marked change in the past 10–15 years. Technological advances and improved roads and transportation have created new links to metropolitan areas. Rural products now are more likely to be sold to national and international markets, creating a greater interface with the outside world (Hobbs, 1992). For better or worse, rural America is less isolated from mainstream America than in the past. Some communities have been quick to adapt to change; other communities are characterized by a heightened wariness of outsiders and resistance to new ideas.

Rural Families

Effective practice of rural school psychology is also based on an understanding of rural families (Helge, 1985). Media images portray the rural family as embracing traditional values, sheltered from crime, hard working and tightly-knit. Children are seen as benefiting from the support of a stay-at-home mother and an extended, multigenerational family. While seldom depicted as wealthy, rural families are nevertheless thought to enjoy the good life (Hobbs, 1992).

The reality of the rural American family may be very different from idealized images, however. As previously noted, there is a disproportionately high number of rural families in poverty. In impoverished areas, children are likely to live in substandard housing and suffer from poor nutrition. Rural residents are more likely than their urban counterparts to have serious and severe health problems (Gesler, Hartwell, Ricketts, & Rosenberg, 1992). Furthermore, the rise in economic problems experienced by rural families has been accompanied by an increase in mental health problems — particularly stress-related problems — in rural areas (Hobbs, 1992). Findings from a series of studies conducted in the 1980s indicated that rural families have experienced an increase in chronic depression, suicide, alcoholism and other substance abuse, and spouse and child abuse (Helge, 1992). In some communities, teen pregnancy rates are high. Unfortunately, many rural communities lack adequate medical and mental health services; and even when such services are available, families often cannot afford treatment because they lack medical insurance (Hobbs, 1992). The lack of public transportation also makes it difficult for rural families to gain access to needed resources.

Once tightly-knit rural families also are unraveling in other ways. Economic dislocation in rural areas has caused an increase in separation and divorce, and a concomitant rise in the number of female-headed single-parent households. Many rural women have little formal job training, but must now support themselves and their children. As a result of these economic and societal changes, rural women are entering the paid work force in record numbers (Luther & Todd, 1992). Parents in rural areas may commute long distances to work, and consequently many rural districts have witnessed a dramatic increase in the number of latchkey children (Hobbs, 1992). Most rural communities lack adequate child care, preschools, and after-school programs (Luther & Todd, 1992).

It is also important to note that rural families are no longer isolated from the influences — positive or negative — of the media. Most families in rural areas now watch the same television shows and videotapes as their urban counterparts, and purchase the same products as do city dwellers (Hobbs, 1992).

Rural Schools

Besides understanding the characteristics of rural communities, effective practice of rural school psychology also requires knowledge of the characteristics and history of rural schools. In the late 1800s and early 1900s, school improvement efforts focused on urban schools, particularly the challenge of preparing large numbers of foreign immigrant children to work in industrialized America. During the first half of this century, many states attempted to impose an urban-industrial model of schooling on rural communities — a "one best system of education." Despite the absence of empirical data on the effectiveness of rural schools, the schools were nevertheless characterized as poorly organized and inefficient, offering an outdated curriculum, and lacking in intellectual stimulation. Bigger was seen as better. There was a push towards school consolidation and control of rural schools by professional educators, who were said to know more about the educational needs of rural youth than the lay people of the local community. Thousands of small rural schools were closed between 1900 and 1960, despite the protests of rural citizens (DeYoung, 1987; Nachtigal, 1982).

In the mid-1980s, educational researchers began to take a closer look at the strengths as well as the problems of rural schools. The view that small rural schools necessarily provide an inferior education began to be reevaluated. It was recognized that the poor academic achievement and high student dropout rates found in some rural areas must be interpreted in terms of the pervasive effects of rural poverty, not just in terms of the effectiveness of the school (DeYoung, 1987). Based on a study of school districts in New Jersey, Walberg and Fowler concluded that "generally, it appears that the smaller the district, the ***higher*** the achievement when the SES and per-student expenditures are taken into account" (emphasis added, 1986, p. 20).

As many writers have observed, small schools are now "being rediscovered as models for effective schools" (DeYoung, 1987, p. 135), and growing evidence supports the contention that "the quality of school life in many rural elementary schools equals and often exceeds that found in urban schools" (Muse & Thomas, 1992, p. 47). Some of the characteristics of effective schools often found in rural districts include high levels of teacher involvement in decision making, a sense of pride and "ownership" by the community, and little bureaucracy. Other strengths typical of small rural schools include small teacher–pupil ratios, high levels of individualized attention to pupils, and use of innovative problem solving. Furthermore, cooperative learning strategies and peer tutoring have a long history in multigrade classrooms (DeYoung, 1987; Muse & Thomas, 1992).

Small rural schools face unique and continuing challenges, however. Because of their geographic isolation, the cost of program delivery in rural areas typically is higher per pupil than in nonrural areas (Phelps & Prock, 1991). In many states, funding inequities between rural and urban schools favor schools in metropolitan areas. Local funds for rural schools are tied closely to the health of the local economy, which may be unstable or depressed. Many rural communities have experienced a shrinking tax base due to a loss of workers coincident with an increase in elderly residents (Phelps & Prock, 1992).

Rural schools also face problems of recruitment and retention of qualified teaching and support staff. Attrition rates for school personnel in rural districts are reported to be 30–50%, much higher than attrition rates reported for nonrural schools (Helge, 1984a). This difficulty of recruiting and retaining competent educators means that rural schools may sometimes have less qualified teachers, administrators, and support personnel than nonrural schools (Muse & Thomas, 1992).

In addition, rural districts face unique challenges in the delivery of special education services. Prior to 1975, there were typically no public school programs for children with severe disabilities in rural areas. Many children with severe impairments were institutionalized or simply kept at home. Children with mild disabilities, however, often were included in the regular classroom. After passage of the *Education of All Handicapped Children Act* in 1975, more programs and services became available for children with severe disabilities in rural areas, particularly through intermediate school units or other regional cooperatives. However, a shortage of special education teachers in rural schools continues to exist. Furthermore, because of the small numbers of children with diverse special needs, many rural districts are not able to offer the full continuum of special education alternatives found in nonrural areas (Helge, 1992).

Rural School Psychology

The last paragraphs of this section provide an overview of rural school psychology. Several studies have explored job role and job satisfaction of rural school psychologists. Unfortunately, much of the available research is flawed because of small samples, the failure to adequately operationalize the "rural" variable, and reliance on the respondent's self-report of employment setting (Reschly & Connolly, 1990). Findings from studies of rural school psychology must be viewed as tentative in light of these shortcomings.

Several benefits of rural school psychology have been suggested in the literature. Studies have suggested that, because of the limited availability of other specialists, school psychologists in rural areas are likely to assume a "generalist" rather than a "specialist" role — that is, they typically have the opportunity to assume a broader range of professional roles than their counterparts in suburban or urban schools (Cummings, McLeskey, & Huebner, 1985). In addition, when compared with their nonrural counterparts, rural school psychologists have reported greater influence on school policy, more time spent in consultation and less time devoted to assessment, and a greater emphasis on boundary-spanning functions (i.e., coordination of people and resources) (Huebner, McLeskey, & Cummings, 1984; Jerrell, 1984).

Rural school psychology, however, also poses special challenges. Rural practitioners may encounter poor travel conditions, few appropriate program alternatives for children with special education needs, and a shortage of teachers with specialized training for work with children with behavior or learning problems. Furthermore, the lack of mental health specialists in rural areas may make it difficult to ensure that children and families receive needed mental health services (Helge, 1990).

Recent studies of rural and nonrural school psychologists typically have found no significant differences in salary and other compensation (Ehly & Reimers, 1986; Reschly & Connolly, 1990). Interestingly, several studies have reported no differences in overall job satisfaction in comparisons of rural and nonrural school psychologists (Ehly & Reimers, 1986; Reschly & Connolly, 1990). Many practitioners, however, report professional isolation as a major source of dissatisfaction with the rural setting (Benson, Bischoff, & Boland, 1984). For example, rural practitioners may have limited access to professonal libraries and up-to-date assessment and remediation materials, and they may be isolated from opportunities for consultation with peers. Entry-level practitioners in isolated rural schools may have difficulty finding qualified school psychologists to supervise their work. Although some studies suggest that rural practitioners participate in professonal development activities as frequently as their nonrural counterparts do, those activities may be designed for teachers rather than psychologists. Thus, there may be few local continuing education opportunities specifically appropriate for the professional development needs of psychologists (Benson et al., 1984; Helge, 1985; Solly & Hohenshil, 1986).

In discussing the special challenges of rural school psychology, one must also consider the entry and adjustment of the new practitioner to rural community life. Personal isolation and dissatisfaction with community life may be more important factors than job role or satisfaction in determining retention of school psychologists in rural schools. Little research has appeared on practitioner adjustment to rural community life. The literature on teacher shortages, however, clearly suggests that "rural culture shock" is a key factor in teacher attrition in rural schools (Helge, 1992).

The benefits of rural community life may include scenic beauty, opportunities for outdoor recreation, high-quality family life, and lower levels of crime and violence. School psychologists who accept positions in rural schools may have difficulty finding adequate housing and gaining acceptance in tightly-knit communities, however. Some rural areas have no apartments and little available rental housing. In some communities, practitioners may be respected as professionals, but never gain full social acceptance. Teachers who stay in rural districts are likely to have been raised in rural communities and to be married. Unless school personnel make an active effort to create a social network, there may be few social opportunities, particularly for practitioners who are not married. Teachers in rural communities often report a loss of personal and family privacy because of the visibility and interdependence that characterize sparsely populated areas. There may also be limited access to shopping and cultural events, particularly if weather conditions make travel difficult (Helge, 1992). Rural school psychology is not for everyone.

BEST PRACTICES

Consistent with other chapters in this volume, this overview of best practices in rural school psychology focuses on the delivery of broad-based consultative services. Within this framework, practitioners are encouraged to adopt a collaborative problem-solving approach with the goal of planning effective interventions. The section begins by discussing how to establish effective consultative relationships in small rural schools. Best practices in the delivery of services to teachers and pupils, families, and schools in rural communities are then discussed, including identification of technological advances that may enhance service delivery and create new educational opportunities for rural youth. The "best practices" portion of the chapter closes with a summary of strategies for continued self-renewal in rural settings, and identification of ways in which training programs might improve placement and retention of school psychologists in rural areas.

Establishing Effective Consultative Relationships

One key to establishing effective consultative relationships in rural schools and communities rests on an understanding of the role of the rural school principal. Urban schools typically employ a number of administrative specialists, including directors of special education, vocational education, transportation, personnel, and program evaluation and research. In contrast, the rural school principal often bears sole responsibility for educational leadership and ensuring quality programs and instruction for the students within his or her building.

In many rural areas, school psychologists are employed by an intermediate school unit or other regional cooperative. They may be housed within a rural district or provide itinerant services. Whether they are employed by a regional cooperative or by the school district, entering practitioners must recognize the significant role of the building principal in the functioning of rural schools. To establish effective consultative services, it is critically important for the rural practitioner to meet with each school principal to discuss the nature and scope of services he or she has to offer, to identify — and perhaps negotiate — professional roles and service priorities, and to seek agreement about procedural issues. It is also important to establish communication channels to ensure each principal is kept informed about services being provided within his or her building. In rural communities, parents and teachers with questions or concerns about the psychologist's activities are likely to contact the principal, and he or she must have the information necessary to respond to their concerns. Without the sanction and support of the principal, it is extremely difficult for a psychologist in a small rural school to gain and maintain credibility and acceptance among school personnel and the community.

A second key to maximizing consultation effectiveness in rural schools and communities rests on an understanding of social power. Interpersonal or social power is the potential of one individual to affect the attitudes, perceptions, and/or behavior of another (French & Raven, 1959). Two forms of social power are available to the school psychologist in consultative relationships: "expert power" and "referent power." With expert power, the consultee (usually a teacher or parent) perceives that the consultant (school psychologist) has the skills or knowledge that will help him or her accomplish goals. Teachers, parents, and other school staff are likely to seek the help of those they believe are expert in the area of a problem. Referent power, in contrast, is attributed to the consultant when the consultee identifies with him or her. This identification is likely to occur when the consultee perceives the consultant as someone with feelings, attitudes, and behaviors similar to his or her own (Martin, 1978).

The goal in consultative relationships is to achieve a balance of power between the consultant and the consultee. When the consultant and consultee share coordinate status, an open exchange of ideas is likely to lead to effective collaborative problem solving. The consultant brings his or her specialized knowledge of behavior and learning to the problem-solving situation; the consultee brings his or her specialized knowledge of the student(s), the setting, and his or her own role (teacher or parent). To be perceived as credible and approachable, the psychologist must have some measure of both expert and referent power.

As Fagan and Hughes (1985) observed, in many rural settings, the school psychologist must learn to rely more on his or her referent power than on expert power to maximize consultative effectiveness. School psychologists who enter schools in middle-class settings typically are afforded status and some measure of credibility — that is, expert power — on the basis of their graduate degree and specialized training. Personal characteristics (older, more experienced, professional demeanor and attire) may enhance their perceived expert status (Martin, 1978). In contrast, middle-class practitioners who enter schools in isolated, economically depressed rural settings may discover that many parents and some school personnel dislike, discount, and mistrust outsider-experts with "fancy" college degrees and titles. Consequently, knowledge of how to maximize referent power while building expert power is essential for success in some rural settings.

An important strategy for developing referent power is getting to know members of the school community, and allowing members of the school community to get to know you. This may involve spending time in the teachers' lunch room, engaging in small talk with the school secretary, and helping with school projects unrelated to job role (Martin, 1978). In addition, Helge (1992) encourages school professionals who are new to rural settings to take an interest in community events and accept invitations to social gatherings. These suggestions are based on the observation that person-to-person communication and informal power networks are highly important in rural communities (Helge, 1992), and the view that the school psychologist and members of the school community can best get to know each other in informal settings (Martin, 1978).

In interactions with school-community members, the entering school psychologist needs to emphasize ways in which his or her interests, attitudes, beliefs, values, and concerns are similar to those of school-community members. In addition to emphasizing commonalities, practitioners need to use empathetic listening techniques and convey acceptance and respect for others (Fagan & Hughes, 1985). First impressions are important, so the practitioner needs to dress in attire that is not too different from others in the school community. In informal interactions and in consultative relationships, referent power may be enhanced by acknowledging and emphasizing the expertise of others.

As Martin (1978) noted, fostering referent power requires time and opportunities for informal exchange. The itinerant school psychologist consequently faces special challenges in developing referent power. To facilitate entry and acceptance, practitioners need to identify the teachers who are the "opinion leaders" within the school buildings they serve, and seek to provide consultation to those teachers soon after initiating service delivery in the building. Effective work with one respected teacher can go a long way toward enhancing both referent and expert power within a small school. Similarly, establishing a positive rapport with the opinion leaders in the larger school community can facilitate collaboration with others in the community and acceptance among families (Meyer, Parsons, & Martin, 1979).

Working with Teachers

As noted earlier, rural schools often have difficulty attracting and retaining qualified teachers. In order to staff special education programs in rural areas, new teachers, marginal candidates, noncertified teachers and teachers with temporary out-of-field permits, or paraprofessionals may be hired (Ludlow, Bloom, & Wienke, 1990). Because of travel distances, regular education teachers may not receive adequate support from itinerant special education staff in planning individualized instruction for the pupils with disabilities in their classrooms. As a result, teachers in rural schools may feel unprepared to work with the pupils in their classes who have learning and behavior problems, particularly when those difficulties are severe. Rural school psychologists therefore can play an important role in providing instructional and behavioral consultation to teachers in rural schools.

The use of school-based teams to assist teachers in problem solving is gaining popularity in rural as well as nonrural schools (Alkire, 1990; Helge, 1988). School-based problem-solving teams have been given a number of different names, including "pupil assistance teams," "intervention assistance teams" (Alkire, 1990), "mainstream assistance teams" (Fuchs & Fuchs, 1988), and "instructional support teams"

(Rosenfield, 1992). These teams involve a systematic effort on the part of teachers, administrators, and support personnel to plan interventions for pupils with learning or behavior problems. Team goals are to assist teachers in problem solving so that students may be taught more effectively, and to ensure that the diverse educational needs of pupils are met within the regular classroom if at all possible. Pupil assistance teams provide a support system for teachers, encourage a problem-solving approach, and reduce special education referrals. They also provide an incentive for continued professional growth, as team members learn new strategies from each other to improve educational outcomes for children (Alkire, 1990).

Team membership and leadership are likely to vary according to the characteristics of the school and the nature of the referral problem. Based on his experiences in Ohio, Alkire (1990) observed that a key to effective pupil assistance teams in small schools is support and participation by the building principal.

The pupil assistance team literature (see citations above) generally encourages an ecological approach to problem resolution that involves consideration of many factors that affect learning and behavior, including characteristics of the classroom, instructional variables, characteristics of the referred pupil, and support available from the home (Fuchs & Fuchs, 1988). Because of their knowledge of systematic data collection and analysis and instructional and behavioral management, school psychologists have much to contribute to problem identification, planning interventions, and evaluating intervention effectiveness. The practitioner's knowledge of interpersonal communication and group dynamics can help teams function effectively. Furthermore, because of their training and experience in handling confidential and sensitive information, rural school psychologists may also help prevent unnecessary intrusion on pupil, family, or teacher privacy in data gathering and problem analysis.

As Rosenfield (1992) has observed, the development of instructional support teams requires an extended period of time. Psychologists who are interested in developing support teams must establish a positive working relationship with the school, garner principal and teacher support, organize staff training activities related to developing successful teams, plan strategies for ongoing evaluation of team functioning, and plan strategies for evaluating the effects of interventions on referred pupils. However, rural practitioners should be encouraged by the observation that there appears to be a "good match" between the use of pupil support teams and the characteristics of small schools. As noted previously, small schools often have a history of collaborative problem solving, there are fewer bureaucratic barriers to change, and individual professionals may have much influence on school policy. Practitioners interested in developing pupil assistance teams may wish to consult the literature cited above.

In providing consultation to school-based teams or individual teachers, rural school psychologists are advised to recognize and build on the traditional strengths of small, rural schools. In some rural areas, there is a high level of community involvement with the schools and a strong tradition of volunteerism. Classroom interventions might involve the assistance of retirees or other community volunteers. Also, because of the interdependence of individuals in rural communities, children typically are taught to value cooperation in attaining goals. Cooperative group learning methods and cross-age tutoring have a long history in small rural schools, and their continued use should be encouraged.

Technological advances are seen as an important problem solver in rural schools. In a study conducted more than ten years ago, Helge (1984b) found that most rural school systems had at least some types of electronic technology available, with microcomputers available in 88% of the rural districts or cooperatives surveyed. In light of U.S. Department of Education and state-level initiatives (Jefferson & Moore, 1990), a marked increase has likely occurred in the availability of electronic technology in rural areas since Helge's study. From her survey, Helge (1984b) found that computers and other technologies were used to support instruction in a number of ways, including drill and practice, simulation, and educational diagnosis and prescription. School psychologists with expertise in computers and other technologies may have an important role to play in providing consultation to rural teachers. For example, practitioners might help locate and adapt computer programs to the instructional needs of pupils, locate and adapt assistive devices for children with sensory or motor impairments, and help pupils and teachers learn how to use new technologies.

In addition to classroom computers, distance education technologies now promise to break down existing geographic barriers to educational opportunity. Distance education technologies can provide up-to-date knowledge and specialized instruction to students and teachers in remote, isolated schools. Model distance education programs have been developed in Iowa, Kansas, and Utah and, with the anticipated support of the Clinton administration for further development of telecommunication networks, it is likely that all rural areas in the United States will have distance education service before the year 2000. Many different kinds of distance education are available, involving various technologies. Distance education links can be one way or two-way (interactive). If the link is interactive, the "feedback loop" from student to teacher may allow the student to interact with the teacher only by signal (striking a key), by audio only, or by audio and visual. The visual image may be produced by a "freeze frame" system, where still pictures are displayed, or involve a continuous-motion video system (Jefferson & Moore, 1990).

Distance education systems may allow rural teachers to instruct students in their homes or at distant community centers. This will help ensure instructional continuity in rural areas where weather causes frequent and long school closings, or when a serious health problem limits school access for a child during part of the year (Helge, 1984b).

Distance education will also link teachers and students around the state, making it possible for small rural schools to offer a more diverse curriculum. This technology may be particularly helpful for specialized instruction of children with disabilities. For example, close-captioned instruction available via distance education can expand learning opportunities for hearing-impaired students in rural areas. Specialized content available via distance technologies may also provide needed educational challenges for gifted and talented students in small schools. School psychologists may assist in matching instructional resources available via telecommunications to the learning needs of rural youth. Links among public schools and colleges and universities will also provide opportunities for consultation with experts regarding difficult classroom problems, and continued professional development opportunities for rural educators.

Working with Families

In recent years, most states have attempted to improve interagency cooperation in the delivery of human services in order to avoid duplication and cut costs. The school has traditionally been the hub of community life in rural areas, and it is now the center for interagency coordination of services to families in many areas of the country. Because of these changes, the rural school psychologist has an increasingly important role in creating and maintaining links among the school, community agencies and programs, and families to meet the needs of rural children and youth.

As noted previously, children in rural areas historically benefited from the support of an extended, tightly-knit family and high levels of parental involvement in the schools. However, with the increases in poverty and single-parent homes, many rural families now need support from the school and community in meeting their children's needs. In addition, the lack of job opportunities in economically depressed areas has lowered the educational expectations of many rural youth (MacBrayne, 1987). Consequently, in many rural communities, schools now must make a more active effort to work closely with families to raise educational expectations and ensure student success in school.

In all settings, school psychologists must be sensitive to local values and traditions in gaining acceptance among families. While there is ethnic diversity in some rural communities, in other rural areas — particularly those that are geographically isolated — an ethnic or religious minority may be a strong subculture (Helge, 1988, 1992). Some remote rural communities are composed of Hispanic migrants, African Americans, Native Americans, or a religious minority who have little experience interacting with those who are different. Depending on the characteristics of this group, there may be a dislike or mistrust of outsiders, or a high level of conservatism.

In gaining acceptance among rural families, practitioners must make a special effort to learn about the local culture, show respect for customs and mores, and provide opportunities for community members to get to know them in informal settings. Practitioners need to identify the individuals within the school community (e.g., a well-respected teacher or school nurse) who can smooth the way for work with families within the area. Home visits made with a well-liked teacher or school nurse and tours of local industries can often bring important insights into family and community life.

Helge (1992) cautions practitioners that the right to self-determination is highly valued in many rural cultures. Consistent with the literature on effective consultation, it is important that school psychologists working with rural families communicate respect for the family's right to make choices. For consultation with families to be effective, the consultant must provide alternatives and the knowledge necessary to make good choices, rather than imposing solutions.

There is now a growing understanding of family influences on student competence in school. As Epstein (1986) has observed, parents want their children to be successful in school, but many do not know how to help their children succeed in the school setting. Based on a review of the available literature, Christenson, Rounds, and Gorney (1992) identified a number of family factors that affect achievement in school, with special attention to those that can be altered through intervention. This literature shows how educators might work with families to improve school competence and learning. Interventions designed to raise parental expectations for the child's academic performance, improve home support of academic learning, increase parental involvement in schooling, and create a more supportive affective home environment all promise to improve student outcomes. Helge (1992) has suggested that it is also sometimes important to help families learn how to be effective advocates for their children. Rural families may not be aware of the legal rights of children with disabilities, and they may not know about available resources or how to access those resources within the school or community.

As noted earlier, rural families have experienced an increase in stress-related mental health problems, including substance abuse and child abuse, but there is often a shortage of health and mental health professionals in rural communities. In planning interventions to improve home conditions for children, school professionals need to recognize the important role of paraprofessionals and volunteers in providing assistance and support to rural families. Parent discussion and support groups led by paraprofessionals and volunteers often are more successful in rural communities than programs offered by professionals (Helge, 1992). As Helge observed (1988), rural family members will listen to friends and neighbors more easily than they will to professionals. Thus, it is important that rural school psychologists work to support, rather than supplant, existing helping relationships in rural communities (Keenan, Dyer, Morita, & Shaskey-Setright, 1990). School psychologists may play an important role by offering their expertise to the nonprofessionals involved in helping systems. In this way, the effectiveness of existing helping systems may be improved, providing greater benefits to rural children and families.

Consultation to Schools and the Community

Recent school reform efforts have produced greater emphasis on systematic evaluation of educational programs and student outcomes. Program evaluation results can be used to modify program design and instruction to improve student learning. As Helge has observed, systematic program evaluation is particularly important in rural schools because such efforts can "provide data to defend programs in an era of declining resources and school consolidation" (1987, p. 60). Unfortunately, rural schools typically lack staff trained in program evaluation. Because school psychologists are knowledgeable in research design, they may play a significant role in program evaluation.

School psychologists may also play a significant consultative role in rural schools by researching the availability of state and federal grants for improvement of educational programs. In 1978, Sher published an influential paper criticizing the lack of federal government attention to the problems of rural schools. Since that time, the U.S. Department of Education has made a greater effort to provide funds to improve rural education. Rural school psychologists who are (or become) knowledgeable in grantsmanship may be able to assist rural schools in obtaining funds for program improvement.

School psychologists also may have an important role to play in providing consultation to rural communities. In many rural areas, the school is the center of community revitalization efforts. Rural educators and businessmen have recognized that they must have an educated work force to attract much-needed industry, and jobs must be available to keep educated adults in the community (Hobbs, 1992). This interface between education and the economic development of the community can create exciting opportunities for rural school psychologists. Rural practitioners may become involved in various school-community improvement efforts, including the development of day care, preschool, and after-school services and the development of vocational training opportunities for youth and adults.

Strategies for Continued Self-Renewal

This section provides a brief overview of strategies to avoid job burnout, reduce professional isolation, and create opportunities for continued self-renewal in rural areas. One factor known to be associated with job burnout among school psychologists is role ambiguity (Huberty & Huebner, 1988). The role of the school psychologist may be misunderstood in rural schools and communities (Helge, 1988). In addition, psychologists who are employed by regional cooperatives may encounter conflicting role expectations from the regional office versus local districts (Benson, 1985). In order to avoid role ambiguity, rural school psychologists are wise to negotiate their job description during the hiring process, taking time to clarify roles and priorities in discussions with regional and local school administrators. Periodic review of job goals and priorities with supervisors and building principals is important to ensure continued role clarity and reduce the likelihood of burnout.

In many rural areas, poor travel conditions can add to job stresses, particularly for practitioners who provide itinerant services. Use of a C.B. car radio or a car phone can help reduce travel-related stress by allowing the school psychologist to communicate with schools or parents while traveling. Such devices ensure help will be received if travel emergencies arise, and allow for the timely rescheduling of appointments in the event of unforeseen delays. The current generation of laptop computers can also reduce job stress by facilitating the efficient handling of paper work at all work sites.

Although rural school psychologists report levels of job satisfaction similar to those of their nonrural counterparts, personal and professional isolation may be a source of dissatisfaction with the rural setting. Rural practitioners who provide itinerant services and/or work as the only psychologist within a district are advised to make a "conscious and deliberate effort" to form a professional support group (Presbury & Cobb, 1985). Support groups can help practitioners solve difficult professional problems and provide a stimulus for continued professional growth. Of equal or perhaps greater importance, however, such groups can be a source of emotional support and give the practitioner a sense of social belonging.

Technological advances also can reduce professional isolation and create continuing education opportunities. Computer bulletin boards can be used to create links to other school psychologists and rural educators (see Lipinski, 1991). Videotapes and the distance education technologies described above also promise to provide continued professional development opportunities specifically appropriate to school psychologists.

Training Programs for Rural School Psychologists

Only a few school psychology programs currently emphasize training of practitioners to provide services in rural schools. The University of Colorado at Boulder and Alfred University in New York have made special efforts in this area. In order to improve placement and retention of school psychologists in rural settings, the following are needed: (a) increased recruitment and training of students from rural areas who are likely to return; (b) increased recruitment of students who have a commitment to rural education and knowledge of the personal and professional challenges associated with rural settings; (c) improved training in skills and service-delivery models needed in rural schools, including supervised preservice field experiences in rural settings; (d) increased availability of quality supervision for entry-level rural practitioners; (e) the development of regional networks to provide professional support for psychologists in rural school settings; and (f) increased availability of professional development opportunities for psychologists in rural settings.

SUMMARY

Effective practice of rural school psychology is based on knowledge of the special characteristics of rural communities, schools, families, and the unique setting in which the practitioner serves. In order to gain and maintain credibility and acceptance, rural practitioners must understand the significant role of the principal in small schools, recognize the importance of establishing positive working relationships with school and community opinion leaders, and know how to maximize referent social power.

Rural school psychology offers a number of professional and personal challenges. Probably the most important broad professional challenge is to work with others in the school community to ensure that all rural children and youth have the best possible opportunities to succeed in school. The goals of providing educational opportunities and ensuring good school outcomes must be met despite many barriers commonly found in rural areas: inadequate funds for schools, a shortage of qualified teachers and other professional personnel, geographic and climatic barriers, cultural differences, and the pervasive effects of family poverty.

Rural school psychology also promises many unique opportunities, as educators rediscover the strengths of small schools and how to build on those strengths, and technological advances provide solutions to the problem of geographic isolation. In addition, in many rural communities, the school is the center of interagency coordination of services to families, and the hub of community economic revitalization efforts. This creates the possibility of many exciting boundary-spanning roles as schools and community join together to improve home conditions, community services, education, and vocational opportunities for rural youth and their families.

ACKNOWLEDGMENTS

A special thank you to Central Michigan University graduate student Christine Richey for her assistance with the library research.

Best Practices in Adopting a Prevention Program

A. Dirk Hightower
Primary Mental Health Project — University of Rochester

Deborah Johnson
Primary Mental Health Project — University of Rochester

William G. Haffey
Monroe Board of Cooperative Educational Services #1 — Rochester, New York

OVERVIEW

Defining primary prevention has proven to be difficult. Indeed, a consensus among authors has not been reached (Hightower & Braden, 1991). However, primary prevention efforts universally seek to change the incidence of new cases by intervening proactively, that is, *before* disorders occur. For example, (a) competencies may be increased through education; (b) training may be provided to help people develop coping strategies to short-circuit negative effects of stressful life events and crisis; (c) environments may be modified to reduce, or counteract, harmful circumstances; or (d) support systems may be developed more fully. Whole populations or groups considered to be "at risk," rather than individuals, are targets for such interventions. Primary prevention efforts do *not* attempt to reduce existing problems; rather they are proactive preemptive efforts to prevent problems from occurring.

Prevention in this chapter means secondary and primary prevention; tertiary prevention is referred to as *treatment*. The essence of secondary prevention is early identification of problems and intervention before problems become severe. By identifying problems in their initial stages, professionals can design interventions to shorten the duration of the problems and minimize their intensity, thus reducing the prevalence of disorders. Frequently, children are targets of secondary prevention because of their psychological malleability and flexibility. The younger the child, the less likely problems will be entrenched and the more favorable the prognosis.

In support of prevention programs, Bloom (1985) states that "if we insist on waiting until all direct treatment needs are met before allocating resources to prevention, we will doom our profession to continuation of the hopeless downward spiral in which we now find ourselves." While school psychology traditionally has not been in the forefront of working with prevention programs, the field's current movement supports and enables school psychologists to become more proactive in providing for a better educational system for our children. Realistically, school psychologists will have to divert more time, money, and energy from direct services, such as assessment and special education, toward working with school systems implementing prevention programs.

The paradigm shift from treatment to prevention can be a small, yet a logical, change for many school psychologists. Whereas many treatment and prevention technologies are, at times, surprisingly similar, conceptual and philosophical distinctions between treatment and prevention are important. In essence, treatment and prevention differ primarily in terms of the *time* of intervention in relation to the period of onset of difficulties and the *target* of such interventions. Treatment programs serve individuals experiencing problems, whereas preventive interventions focus on groups when problems are just starting to emerge or before they occur. The ever present need for more school psychology services, the continuing shortage of school psychologists, and the relatively small gains made in *treating* various learning problems, behavioral conditions, or mental disorders, all point to the need for further adoption of effective prevention programs.

BASIC CONSIDERATIONS

In this chapter, it is assumed that the school psychologist has identified a potential prevention program to adopt. If more information is needed regarding well-documented and available prevention programs for children of all ages and adults, the reader is referred to the end of this chapter, which contains an annotated bibliography, an abridged prevention bibliography, a list of prevention clearinghouses, and a list of journals that routinely feature prevention.

BEST PRACTICES IN ADOPTING A PREVENTION PROGRAM

This chapter considers concrete ways to introduce and conduct school-based prevention programs. The next section focuses on determining if a school is ready to implement a prevention program and introducing such programs into the school. The second section focuses on issues of implementation including program size, staffing, building support, training, and developing realistic goals and objectives. The third section provides suggestions for maintenance of prevention programs and quality control. The later two processes rest on successful system analysis and program introduction.

System Analysis and Prevention Program Introduction

Identifying needs. In any plan for change, the school psychologist must have a clear understanding of system needs and ways a prevention program might meet those needs. He or she must also understand the school system — a step required *before* a prevention program can be proposed.

Prevention programs, like all applied endeavors, must have relevance for, and address the needs of, those who are involved. For school-based prevention programs, this means the needs of the community, the central administration, the principal, the teachers, and students must be addressed. But, until a system's gatekeepers perceive a need, prevention programs cannot start, much less succeed.

How is need identified? One way is to conduct a formal needs assessment. For more information on formal needs assessments see the Nagle chapter in this volume. Hazards of such global needs assessments include (a) identifying more needs than can be addressed and (b) raising expectations unrealistically. If the resources or programs to address the identified needs are unavailable, then the relative good and harm resulting from global assessments should be weighed before starting such assessments.

An alternative to formal needs assessment is to follow one's "sense of the obvious" which is then confirmed by convergence across sources. To do this, the school psychologist must spend considerable time in open discussion and active listening with building staff so as to identify sources of repeated frustration. For example, a colleague conducting numerous individual psychoeducational assessments followed by teacher conferences observed that many elementary students had poor peer relationships and that teachers were aware of and especially concerned about these children. At almost the same time a high school teacher commented, "Kids these days don't even have enough interpersonal skills to work together on a half-hour chemistry lab." In a research project it was noted that many young elementary school children believed it was against the rules to help other children with their work. In their words, "It's cheating!" These observations reflected a convergent message from independent sources and confirmed an obvious need: Many children lack important peer social and cooperation skills.

Delineation of a school's needs offers a framework for developing a hierarchy of concerns, identifying the most important ones, and selecting those that fit the *expertise* and *interest* of the school psychologist. Other relevant questions in this early exploration process include the following: Will staff require training within the selected "need" area? Which interventions have been tried in the past? How can the largest number of students be reached? Across which grades are there common needs?

Addressing such issues effectively through a prevention program will usually require major shifts in the thinking of school personnel. For example, the teaching staff and the school psychologist will need to move away from addressing problems and toward issues of wellness and the development of competencies. For a discussion of this needed change, as well as other resistances and excuses likely to be encountered, the reader is referred to Hightower and Braden (1991) and the chapter in this volume on Promoting Competence by McConnell.

Prevention program review. Once needs and prevention programs addressing those needs have been identified, as much information as possible should be obtained. Attending program workshops, visiting schools and communicating with school personnel who have implemented similar programs, and reading relevant journal articles and research reports are all important aspects of the initial review process. The goal of such inquiry is to thoroughly study each program and to conceptualize how it may best be adapted to a specific need in a specific school *before* it is recommended for adoption. Time spent in these activities will significantly improve the chances of successful program implementation and maintenance.

Introduction of the system. Once the review steps are well under way, the process of introducing any prevention program into the system begins. For school psychologists who (a) have worked for years in the same system, (b) have a good understanding of a school's governance and decision-making processes, and (c) are knowledgeable about the system's entry and negotiation procedures, the following section may be familiar. This section is written primarily for those who are new to the field, who come from an outside agency and are not familiar with the school system's way of operating, or who would like a review of practices and procedures appropriate for prevention program adoption.

Each system should be approached at its *safest* point. Identifying this safest point means that each system should be analyzed or, in clinical terms, *diagnosed* in relation to its functional structures and processes (see Schein, 1969). Gatekeepers, allegiances, managerial styles, and communication pathways exemplify some areas of diagnostic importance. System analysis, though often complex and time consuming, is always necessary. Whatever one's conceptual orientation, the diagnostic process remains surprisingly similar. The point to keep in mind is that an essential first step *before* approaching a system with a new idea is to find out as much as one can about the system, that is, a social history.

Talk to anyone who knows about the system; retired principals or teachers, for example, are often informative sources. Read documents about the system's lineage, strengths and weaknesses, key leaders, and power structures. Helpful documents in this process include minutes of board meetings, policy and procedure handbooks, superintendent's or director's "state of the school" or annual reports, and *budgets*, which are available for most public schools. As an example, one school psychologist, who works regularly in different schools, reads the school board minutes religiously. As a result, she often knows more about what is happening within her school district than the principals!

Remember everything or, better yet, record your impressions, because human memories are limited. Look for convergence. As a general rule, if something appears *once*, remember it; if it appears *twice* from different sources, recognize it is likely to be true and important; and if it appears *three* times from different sources, it is almost certain to be true and important.

In the absence of prior contacts with informed inside sources, starting with the highest levels of administration is one way to enter a system. But it may also be a very dangerous place to start because top administrators have the power to quash an idea immediately, or, worse yet, they may like an idea and proceed to force those below them to participate. For several reasons, the middle management in many school systems, that is, principals, supervisors, or directors of pupil personnel, may be the best place to make an initial contact. Although middle managers typically cannot give definitive approval to new proposals, they are often influential gatekeepers and decision shapers. In addition, middle managers are also familiar with the system's administrative concerns, style, and jargon; thus, they can provide useful cues about the best ways to proceed. For example, in talks with a principal about a new primary prevention program designed to teach third graders assertiveness, communication, relaxation, and problem-solving skills, it became clear that use of the word *assertiveness* made him squirm. During the discussion the principal remarked that the superintendent's focus for the year was to develop students' "coping skills." On the basis of this visit, the initially named Assertiveness Training Program was retitled the Classroom Coping Skills Program. In that form it was eagerly adopted by the school district. Equally important is the fact that if middle managers like a prevention program they have the power to support it from within the system. Such support is a necessary, but not a sufficient, condition for adopting a prevention program.

Although it is often a good idea to begin discussions about new programs with middle managers, eventually others must be involved. A carefully conducted organizational assessment can often provide useful cues about when and how to take those next steps. Answers to the following questions may help in making good decisions about when and how to proceed:

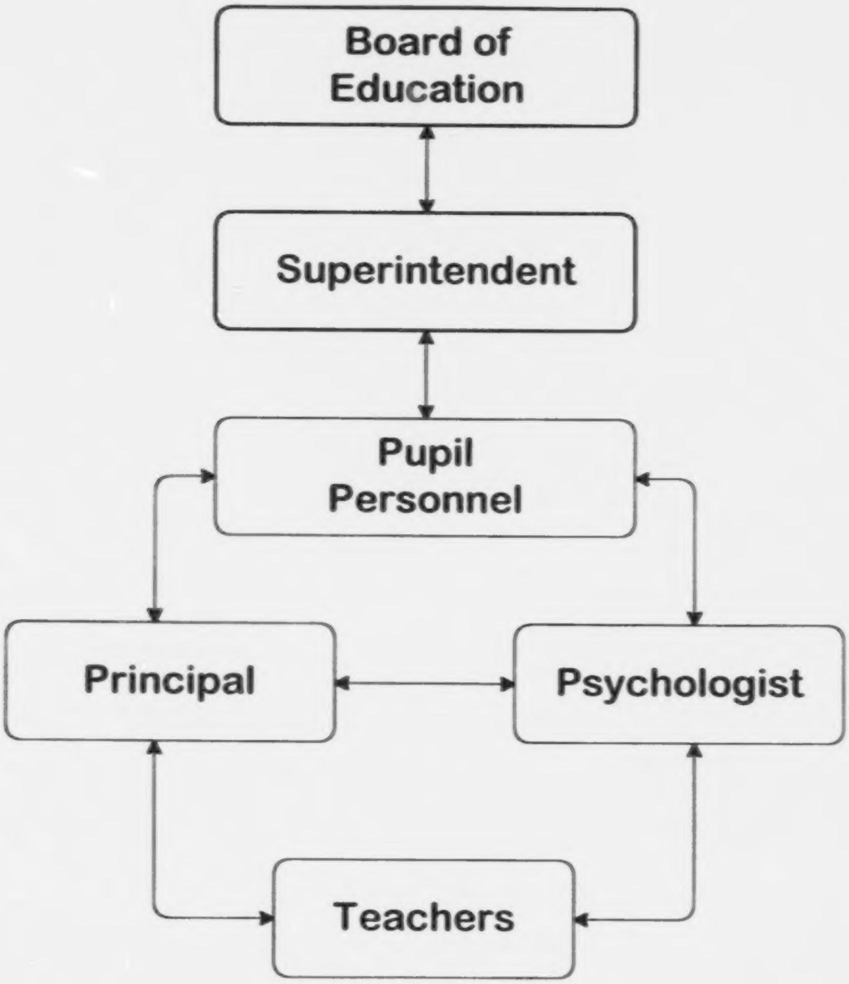
- How do others perceive the principal? The superintendent?
- How and by whom are decisions made?
- Who are the real leaders? Who follows whose lead?
- How does communication take place within the system?
- Who are the "thinkers?" The "doers?"

In assessing a school system, it is helpful to understand a school's de facto power structure, how the system actually operates. Power can either support success or facilitate failure. Two examples follows. Figure 1 depicts a system with considerable potential for program implementation. In this model there are open lines of communication among teachers, the principal, the psychologist, and the pupil personnel director. However, with this or any other structure, negotiations must involve all school staff who will implement or be involved with the new prevention program. Whenever possible, a school psychologist should use a bottom-up mode of communication, that is, have the approval and input of the teachers, principal, and supervisor *before* a proposed prevention program is taken to the superintendent.

Unlike the system presented in Figure 1, Figure 2 depicts a divided system. The two teacher groups often bypass the prescribed structure and deal directly with the Board of Education, which apportions only superficial power to the central administration. The psychologist can be caught between the teacher groups, trusted by neither, and rendered powerless. Such a system, concerned as it is with internal power struggles, is typically not ready for any new programs.

In summary, system analysis is needed to establish either that a prevention program is potentially feasible and how best to proceed or that a system is not ready for the introduction of change. In the au-

FIGURE 1. Healthy school district organization.



thors' experience the entry process works best if the school psychologist keeps three considerations in mind:

1. School systems do not always function as one might infer from their tables of organization. Knowing how a system actually functions helps the school psychologist proceed in ways that can best advance program objectives.

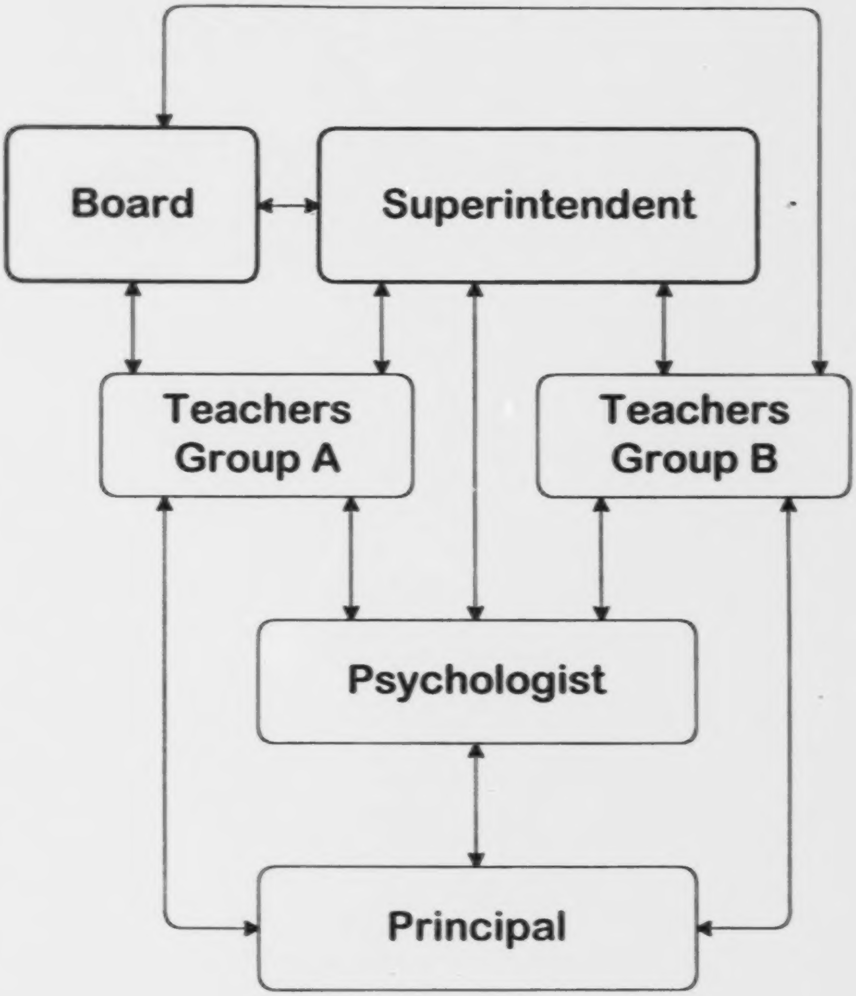
2. Getting a new program started requires considerable time and respect for district procedures. Patience, sensitivity, and persistence are necessary for the long run.

3. It is prudent to develop solid support from those who will be impacted by the program, as well as the system's middle managers.

In many ways the process of introducing a prevention program into a school is like introducing any other program. "Professional small talk" and the initial presentation, however, can be of particular importance in introducing prevention programs.

Professional small talk. In many situations, before a prevention program is introduced, the first order of business is professional small talk (PST). A goal of PST is to develop a professional relationship between the school psychologist and relevant school personnel that is characterized by trust, respect, good communication, and understanding. Developing such a strong professional relationship enhances the likelihood that a prevention program or even a pilot program can be started. Because prevention is an ab-

FIGURE 2. Unhealthy school district organization.



straction to many, the more specific the program description and its objectives, the more likely it will be understood and attempted. On the other hand, if the working relationship between the school psychologist and school staff is weak or poor, even the best prevention program does not have a chance of getting started. The point is that the time invested in establishing effective working relationships with school personnel can contribute importantly throughout the adoption processes of a prevention program.

Initial presentation. After the needs assessment, program selection, system analysis and entry processes, an initial program presentation is made. This is an important step, which, when properly taken, can set a positive tone for the entire program. The two main goals of such a meeting are to provide basic information about the program and to answer questions. Some guidelines that have been found useful in making such presentations follow.

It is important to anticipate which types of information will be relevant to the host and to address those points. These concerns typically center around the program's rationale, goals, objectives, target group(s), and specific procedures. One way to identify salient information is to formulate a list of likely questions from those involved in the presentation and to develop clear answers to all such questions. This procedure can be further enhanced by consulting with people who know the system well and soliciting other concerns from them.

The following are examples of questions frequently posed at meetings introducing new prevention programs.

- How will the new prevention program interfere with ongoing programs or curricula?
- Does this prevention program duplicate Ms. X's efforts?
- How will the program's effectiveness be assessed?
- Have others run similar programs? What did they find?
- Who will pay for this program?
- Who will be hired and what will be their credentials? Can we use Ms. G from our staff?
- What does the teachers' union think about this program?
- Whom should parents call if they have a question?
- Why implement this program now?

These questions are representative, not exhaustive. The key point to stress is that concerns should be anticipated to the greatest extent possible *before* starting. Also, essential consumer information should be provided, and false turns should be minimized. If unanticipated questions arise for which clear answers are not available, it is best to indicate that you will find out the answer and get back to the concerned individual than it is to make up an answer.

Another suggestion for the initial presentation is to limit the opening program statement to 10–15 minutes, and then say something like, "Let me stop here and answer your questions." This will enable the audience to clarify points they have missed, raise questions, and identify matters that may need more in-depth coverage.

It is not safe to assume that what is said during a presentation will be remembered *accurately*. Before making a presentation, a brief, two-page, written proposal should be developed. (A one-page proposal is probably too short to do the program justice, and more than two pages is too long for the reader's interest.) The clearly written proposal should be simple and straightforward and should answer: Why Who will doing What with Whom, When.

The proposal should include a catchy nonjargon program name appropriate to the host school. For example, "Wings," "Special Friends," "Growth Center," "Project Try," "Primary Intervention Project (PIP)," and "Primary Project" are all adaptations of "Primary Mental Health Project." The latter title, though descriptive, may include potentially negative associations. Given that a program's name is used more often than anything else associated with the program, it helps to choose a name with a positive connotation. Naming a program also expedites the transfer of program ownership.

Other points to include in the brief written description are succinct statements of (a) the program background and rationale, including brief references to past relevant research; (b) the program's central goals and objectives stated in concrete and specific terms; (c) a program description, including its basic structures and activities; and (d) a listing of responsibilities of relevant program and school staff. An appendix can include drafts of letters and permission forms for parents, sample curriculum materials, a reading list, and a budget. This does not necessarily mean that all audiences should receive all these documents; each audience should receive only a set of documents pertinent to it. Unless the written materials will be referred to in the verbal presentation, documents should be handed out *after* the presentation, so that attention can be focused on the presentation.

The authors have also found it helpful to assume that the middle manager *might* have useful notions about how best to proceed with a program. That assumption orients one to the following questions: "From your perspective, what would you suggest is the best way to proceed from here?" or "What next steps need to be taken?" Such questions put school staff in an active participant role and enhance their sense of project ownership. School people can respond to such queries in several directions: (a) "I'll take it and run with it" or (b) "You need to do X, Y, and Z." The confidence you place in your system analysis often structures how best to proceed. For example, before a meeting with a known and trusted pupil personnel director about implementing a prevention program, it was assumed that *he* would take the proposal to the superintendent. Instead, he recommended:

> I can take it to the chief, but then I would have to defend it. If you mail it to him, he will seek my advice and approval, which I have no problem giving. I think that's the way to go this time because I've been asking for a lot of things lately.

His suggestion was followed and the scenario unfolded as he predicted.

Another guiding principle is to recognize that systems move slowly and that due process and realistic timelines must be respected. After an initial presentation, several months lead time may be needed before a preventive program can actually start.

Although it is helpful to describe evaluation components as *part* of the program from the beginning, there may be points of conflict between evaluation and service components. In such instances, evaluation ideals may need to be modified to respect pressing service needs. In most cases, however, a compromise can be worked out that addresses both sets of concerns satisfactorily. Also, experience has shown that in an applied setting, the term *program evaluation* is better received than the term *research*.

Finally, before the initial presentation meeting ends, action steps to be taken should be specified and

TABLE 1
Processes of Implementing a Prevention Program

1. Understand the needs of the school.
   a. Formal needs assessment, and/or
   b. A "keen sense of the obvious."
2. Conduct a system analysis observing:
   a. Communication and interaction pattern.
   b. Leadership and decision-making styles.
   c. Staffs' conceptual and motivational strengths.
   d. The system's power structure.
3. Choose a well-documented validated program that meets the school's needs.
4. Develop internal allies who can assist in all stages of program development.
5. Allow enough time for the program to be understood.

a set of *contracts* (Cowen, 1985) about the responsibilities of all concerned parties should be established. In other words, it should be clear who will be doing what by when in order for the program to proceed smoothly.

The preceding paragraphs are practical rules for an initial presentation and an important step in the overall implementation process for a prevention program. Although it helps to think through these matters carefully before making the initial presentation, professional skill, wisdom, and sensitivity need to supplement these basics.

Summary of diagnostic and introductory steps. The essential processes during the early stages of implementing a new prevention program are reviewed in Table 1. In sum, the ultimate goal of these steps is to maximize the likelihood of successful program implementation by paying close attention to a system's characteristic ways of functioning, due process, procedures, and human sensitivities.

Implementing a Prevention Program

Although the diagnostic, implementation, and maintenance processes associated with prevention programs are considered in separate sections of this chapter, these processes occur simultaneously. Clearly, good system analysis will advance the introduction and implementation of a program, and effective implementation, in turn, facilitates program maintenance. In essence, however, all these processes are intended to advance the same goal: to develop a successful, durable prevention program. Some frequently asked questions about prevention programs' implementation processes are discussed next.

How big should the initial program be? It is best to start small. The main reason is that most schools have had little experience with such programs. The *paradigm* shift required to provide services to students *before* serious problems are evidenced takes time. Although school personnel may endorse the idea of prevention as an abstraction, concerns may develop, for example, when services are to be provided to a relatively healthy Nathan before a "problem ridden" William. Starting small, that is, targeting a single grade in one school instead of four grades in six schools, allows for careful program scrutiny and a focus on quality control. Smaller implementations permit the school psychologist a chance to address thoughtfully the inevitable "brush fires" associated with new programs and to give all parties involved the attention needed. Also, a successful pilot program can provide a solid foundation on which the school psychologist can build effective programming in future years. Starting small costs less, leaves more room to address mistakes, reduces administrative worries, provides valuable experience to program implementaters, and provides a basis on which to decide whether the program merits more widespread dissemination.

Who should be involved in a prevention project? It is important for the school psychologist to determine, as much as possible, who will participate in and staff a prevention program. The best school-based prevention programs available will fail if the wrong persons are involved. The persons who enhance the chances of success include those who (a) have a good understanding of school systems and their general operating procedures; (b) demonstrate good interpersonal skills with students, parents, faculty, and administrators; (c) understand the prevention program; (d) are motivated to learn and receive training in the skills needed to implement the prevention program; and, most importantly, (e) *want* to be involved.

If school faculty are involved in a prevention program, "wanting to be involved" may be the only variable over which a school psychologist will have control. Frequently, those faculty members who volunteer to participate embody the characteristics just described. Faculty should *not* be forced to participate.

BEST COPY AVAILABLE

In fact, forcing faculty to participate usually creates ill will and inspires program sabotage.

If new staff are to be hired for a prevention program, personnel with the attributes just listed should be sought. Most institutions have specific policies and procedures for hiring and these need to be consulted. In general, it is better to have
flexibility in hiring. In addition, asking trusted faculty or colleagues for referrals is a good method: Over the years, we have found word of mouth to be more productive than newspaper ads in finding good staff. Of course, depending upon the strength of the various collective bargaining units, seniority may be an issue. If so, asking experienced staff with desirable virtues to apply for the prevention program position may be a solution.

Once applicants are identified, several independent interviews are recommended to finalize the selection process. For example, to select nonprofessionals to work individually with primary grade children as "special friends," the interview team frequently includes the project coordinator, the school principal, a teacher, and a school mental health professional. When consensus from different perspectives exists regarding the appropriateness of an individual, there is rarely dissatisfaction and the prevention program thrives. Of course, this process may consume a lot of time, even months, and many persons may have to be interviewed before consensus is reached. However, without consensus among interviewers, difficulties can develop. In sum, the time spent to recruit excellent staff, even if it seems excessive, is time well spent.

Communicate to whom, when? Communication regarding a prevention program should be planned, ongoing, and systemic. Plans should include appropriate communication with each level of the hierarchy. For example, school boards, superintendents, and other district administrators are typically interested in the program's general goals, efficacy, fiscal costs, school district liabilities, and responsibilities. These groups typically want the "big picture." They need yearly updates of the program's activities and accomplishments. Indeed more frequent updates are recommended during a program's first 2 or 3 years.

As much information as possible about a prevention program should be communicated to the principal. A principal's routine communications involve parents, teachers, district administrators, and the superintendent. As strategic gatekeepers, principals can enhance a program's support and success or increase the likelihood of foul-ups and failure. Program updates for the principal should occur at least weekly for new programs and monthly for more seasoned ones. Those implementing a prevention program need to communicate with their principal often enough to generate enthusiasm and support for their prevention program during budget crunches and brush fires. The more a principal perceives a prevention program as a necessary part of the school's continuum of services, the more likely the program will endure.

Teachers also need to know the basics of most school-based prevention programs. If they are not directly involved in implementing a prevention program, *their* students may be. Although teachers are directly responsible for only their respective classrooms, a loss of their support can jeopardize preventive services not only in that teacher's classroom, but also in the rest of the school. Accordingly, weekly and sometimes daily communication with teachers is advisable. Communicating with teachers is no less important than similar processes with the principal, but it may be of lower priority when competing demands limit available time.

Parents should be informed by mail and/or phone about all programs. At times parental permission will be required, so a letter sent home describing the program and asking for permission will be built into the program. If prevention programs are part of a formally adopted curriculum, parent permission for a child to participate may not be needed. Even so, good communication about the prevention program is needed. Parents can advocate for a prevention program, but only if they are informed about it. In the 50+ collective years of experience with prevention programs represented by this chapter's three authors, parents have *rarely* sabotaged an effective prevention program, *if* they have understood it. Hence, feedback to parents is needed from the time a program starts and while it is in progress.

Reporting prevention program elements in school and community newspapers, by way of letters home from the principal, and on local radio shows usually enhances community understanding and support. And, because a fundamental goal of many prevention programs is to enhance support from families, peers, the school, and the community, adequate information to these constituents increases the chances that program support, acceptance, and success will result.

How important are support networks for prevention practitioners? It is helpful, if not critical, to develop and maintain support networks among prevention practitioners both within and across programs. Support networks are defined here as groups, the smallest group being two people, who are able to support, encourage, inspire, assist, reassure, and strengthen each other in the face of day-to-day operations and during occasional, and even more formidable complications. Support networks that reflect these capabilities do not happen by chance; they take time and effort to develop.

Program support can be facilitated by planning and scheduling regular meetings. Meetings can be (a) formal, with participants sitting around a table and following an agenda; (b) informal, meeting in the hall or faculty room over a hot or cold liquid refreshment; or (c) via the telephone with someone who is experiencing or has experienced a similar situation. For those starting a program, it is recommended that formal meetings be regularly scheduled. Informal and telephone contacts should occur as needed but may also be scheduled as routines necessitate. Time spent over cups of coffee may seem like a luxury in a hectic schedule, but in reality it may be some of the most valuable time spent in building and maintaining support. It takes time to be supportive and to receive support, so it is necessary to plan for such time accordingly.

Timeliness is an important dimension that needs to be designed into a support network. At times almost instantaneous responses will be needed. The more critical an issue is *perceived*, the quicker the need for a response. For example, if someone is supposed to be available to answer questions or facilitate problem solving, but does not answer the phone, perceived support could easily be zero. In this case the support network may actually have a negative impact. In most cases, prevention program emergencies do not require immediate responses but do require timely responses. In sum, tardy responses produce insecurity and anger; timely responses build support and trust.

How important are consultation and problem-solving skills in implementing prevention programs? Consultation and problem-solving skills are key to building strong prevention programs as well as support networks. The saying, "Give me a fish and I eat for a day, teach me to fish and I eat for a lifetime," accentuates the philosophy needed. Most school personnel would rather be guided over rough spots than told how to accomplish certain tasks. A goal should be to develop a "we" versus a "they" orientation so the responsibility for the success or failure of a prevention program is not localized in a few (i.e., primarily the program school psychologist) but rather generalized across many: the school staff, parents, and the community. In addition, and almost paradoxically, the greater an individual's sense of responsibility, accomplishment, and control, which are processes accelerated by good consultation, the greater the perceived support from others.

How important is training? Quality training enhances the likelihood that a prevention program will succeed. When various program participants know *how*, *when*, and *why* they are supposed to do various tasks, they feel empowered.

Good training articulates needed materials and those for whom a program is appropriate. It also clarifies which program elements are: (a) *necessary* for successful program implementation, (b) *likely to improve* the chances of realizing the program's goals, and (c) *open to modification* without detrimental outcomes. Adoption of a successful prevention program is not easy and requires careful attention to training those involved.

As much as possible, prevention program training should be relevant and fun. If training is boring or irrelevant, school staff will find excuses for not attending or leaving early. It is important to keep training meetings as short and as task oriented as possible. Even though school staff may be experts in providing instructional materials to others, they may not be experts in prevention programs. In fact, the more concrete and specific the training, the more effective it is likely to be. Good general teaching principles apply here: first *tell*, then *show*, and finally *let the trainees practice* what needs to be done before they return to their particular schools.

Prevention training should accentuate the positive. Prevention trainers should look for and mention first what has been accomplished best, no matter how difficult it is to find. Following the positive, assistance can be given as to what might be done better. Well-timed constructive criticism is a difficult diplomatic process that taxes consultation skills to their maximum.

Prevention program trainers must also be flexible and sensitive to important issues. Issues that may interfere with learning about how to conduct a prevention program may, at times, intrude and have to be addressed. An example of such a pressing issue might be a recent school board resolution limiting school personnel salaries. Like children with life stressors, school personnel may need to deal with vital matters before learning new material. On occasion, it is better to provide time for such discussions in order that productive time can be spent in prevention training.

A pleasant atmosphere can also help make a more conducive learning environment. Training is usually enhanced by refreshments and comfortable rooms.

How should prevention programs be integrated into schools? To whatever extent possible, prevention programs should be integrated into existing school structures and processes. For example, one structural component of the Primary Mental Health Project (PMHP) is early detection and screening to identify children who show early signs of school adjustment problems. Instead of having a separate screening process just for PMHP, many schools have incorporated PMHP screening into their existing kindergarten screening process. Both time and efficiency are maximized. The point to stress is that it can help, while reviewing a prevention program, to focus on how and where the program will fit into the totality of existing programs and services.

Should those adopting a "successful" prevention program evaluate their efforts? *Every* prevention program should incorporate an evaluation component. (See Keith, in this volume, "Best Practices in Applied Research.") Because adoption of a prevention program is at best difficult, both formative and summative evaluations are needed to determine if a program has been successful, if program goals have been attained, and where improvements might be made.

How can a prevention program be funded? Prevention programs are rarely, if ever, mandated by those who govern schools. Developing funding sources for such programs is, therefore, an important issue. Although seeking fiscal support from school boards is an obvious place to start, that does not always work initially. Recently, state departments of education and mental health have released Requests for Proposals (RFPs) for various types of prevention programs. In general, state agency applications for program support tend to be much shorter, less involved, and less time consuming than federal agency grants. Buzz words from states to look for include "Youth At Risk," "Drug and Alcohol Education," "FOCUS on Youth," "Primary Intervention Projects," "Early Mental Health Initiatives," and other, similar titles. If such RFPs are not available, state school psychological associations and members of the National Association of School Psychologists are well advised to advocate for such resources.

The private sector should also be considered. Private foundations, the United Way, community volunteer organizations, and for-profit corporations frequently look for ways to demonstrate community interest and involvement. Prevention programs that address important community needs have a good chance of being funded, at least on a start-up basis.

Prevention Program Maintenance

Maintaining a prevention program depends upon the many processes used to initiate and implement such a program. Assuming a program has been *successfully* introduced and implemented, primary goals are to foster system ownership and program integrity and efficacy.

System ownership. Fostering system ownership requires: (a) planning from the outset, (b) establishment of support and information networks, (c) integration of the program into the curricular structure, and (d) securing of school district commitment.

Planning from the beginning. Thoughtful planning to facilitate program maintenance should start when the program starts. Even if it proves relatively easy to get a school district to implement a prevention program on a short-term pilot basis, getting a district to maintain a prevention program beyond the initial funding period, past the tenure of the person who starts the program, and over an extended period of time is more difficult. For example, in one prevention project, the project school psychologist did not attend to how the project could be maintained until the final year of outside financial support. Only then did the school psychologist approach the district superintendent, who knew relatively little about the program, to request that project funds be incorporated in the district's budget for the following year. The project was discontinued.

Establishing system ownership of prevention programs takes time. It takes time for a program to become assimilated by the school staff and to be incorporated into the school system. To accomplish this goal there are no simple, how-to recipes available. There are, however, some guiding principles based upon observations of successfully maintained prevention programs.

Support and information networks. Support networks are built from information networks. The more teachers, principals, district administrators, and school boards know about a prevention program, the more they perceive the program to be theirs and the more likely the program will continue. Establishing formal, ongoing communication channels helps program continuity. In one school, for example, the school psychologist strategically requested, and was allowed to review, a prevention program with the school board each February, which also happened to be budget month. His presentation is now a standard part of the school board's February meeting. With little effort, this "institutionalized" progress report can continue after he leaves. Such reports help to keep concerned parties informed and to maintain program support.

Another formal communication channel is a program operations handbook. Such a handbook can be structured and standardized following a specific format, or it can be informal and nonstandardized. An informal handbook can start with a three-ring notebook in which are placed all relevant program memos, letters to parents, minutes of meetings, and copies of presentations to PTAs, school boards, and so forth. Such a notebook/handbook serves as a valuable resource not only for those currently involved with the program, but even more so for those who are beginning with the project and know little of its history.

Program support is also built upon relationships — relationships with positions as well as with people. Key project positions or roles, such as project coordinator, need to transcend the individual. While it is obvious that each person brings specific strengths and weaknesses to a position, essential program functions and relationships must continue when staff changes occur. This means knowledge of important program relationships and functions must be communicated clearly to those who become responsible for a position. This can be accomplished by written job descriptions detailing functional responsibilities enhanced and substantiated by planned briefings. Although the departure of a key person cannot always be foreseen, the codification of basic program information is the best insurance that a program will survive inevitable personnel changes.

Integration of the prevention program into the school's curricular structure. To be maintained in schools, a prevention program will eventually need to be integrated into the totality of school services, as well as the school's philosophies and policies. Prevention programs isolated from the rest of a school's program are not likely to last. Ideally, a prevention program should address some of the more broadly accepted goals of education, the school district, and the school in which it is implemented. One example might be improving classroom behavior and maximizing students' learning. Prevention programs considered to be frills or fads are more likely to be eliminated from school budgets and the school.

School district commitment. Essential to the maintenance of a prevention program is getting local school and district administration to allocate sufficient professional time for completing the program's responsibilities. Because school districts have limited resources, they must allocate those resources according to their priorities. Staff time is the most costly of all expenses. Therefore, when a school allocates staff time to a prevention program, one essential element of program maintenance has been established.

Once again, one obvious way to get support for a program is to ask for it. Although this may suffice as a short-term solution, more is needed for the long term. For continued support, prevention programs need to show concretely what they are preventing and/or which skills they are promoting or enhancing. The formative and summative evaluations suggested previously must address these issues. Nothing breeds support and program maintenance like documented success.

Short-term is defined here as less than 5 years. One critical issue in program maintenance is developing *a realistic time perspective* (Sarason, 1986). Because many prevention programs cannot realistically claim immediate and dramatic results, reasonable and achievable short-term expectations should be proposed.

Program integrity and program efficacy. Once realistic timelines have been established, both formative and summative program evaluations must assess how well the program adoption matches the model and how well the adoption has met its goals. Programs frequently stray from their original model, which can be associated with less than expected results and disappointing outcomes. Therefore, prevention programs need to be monitored to ensure that essential program elements are being implemented faithfully. If they are not, modifications will need to be made. Similarly, if implementation accurately reflects the original model, but the program does not meet its goals, then modification or termination of the program should be considered. Over time, nothing will hurt prevention program adoption and maintenance more than the continuation of inert, ineffective, or harmful programs.

None of these caveats are intended to suggest that a program should be rigid or inflexible, in fact quite the opposite is true. A program as initially implemented may not fully generalize to a different school environment, or it may operate successfully for a number of years and then become less successful. Prevention practitioners must recognize that all systems change. Systems experience internal and external pressures that require good problem-solving skills, flexibility, and alterations. Prevention program implementers must be sensitive to the need for change and plan for it by repeatedly assessing the efficacy of specific program elements and the overall results and by-products of the prevention program.

SUMMARY

Many of the processes involved in adopting a prevention program are similar to those involved in adopting any program. One important difference, however, is the change required in thinking about how best to approach a problem. In schools there is a tradition of working with the most seriously impaired first. School psychology has only recently begun to recognize the significant limitations of this tradition. Many schools and school psychologists, however, continue to focus on casualties of the system. Hence, for many school personnel a paradigm shift (Kuhn, 1970) in thinking is required. Although systems respond slowly to change, small changes in one part of a system can catalyze change throughout the system.

Another important difference in thinking required when adopting prevention programs is a new sense of appropriate "time." It takes time to *prevent* something or to know if something has been prevented. Contemporary society wants immediate results and today's schools are no different. For most prevention programs, immediate positive results are rarely possible. Although changing school professionals' expectations as to what should occur by when — that is, the "magic bullet" syndrome — will not be easy to accomplish; doing so is a major responsibility of those implementing a prevention program.

Finally, most prevention programs available are still in their infancy. Few have been validated across different settings, populations, or time. These realities dictate that restrained optimism should be used when introducing and implementing a program. It also suggests strongly the need for adequate program evaluation strategies to be part of every prevention program. Practitioners need to be innovative, yet not so foolish or naive to maintain programs or practices that produce questionable results or that simply do not work.

Best Practices in Defining, Implementing, and Evaluating Educational Outcomes

Carolyn T. Cobb
Division of Innovation and Development Services
North Carolina Department of Public Instruction

OVERVIEW

The theme underlying *Best Practices–III* is problem solving, with most chapters likely emphasizing practice with individual and groups of students. The intent of this chapter is to overview the nature of and reasons for dramatic changes in public education in this nation, especially in the types of outcomes or goals that must be addressed. The paradigm of schooling is subtly but surely changing from an emphasis on the resources and inputs of education to accountability for the outcomes and achievement levels attained by students. Inherent in this shift is the importance of the *types* of outcomes for which schools are to be held accountable. As schools explore the types of outcomes to set for their students, seek to apply new knowledge about learning, and search for more valid direct (e.g., low-inference) assessment strategies for accountability purposes, the potential roles for school psychologists will expand. The orientation, knowledge, and skills for these roles may be different from traditional areas of training in school psychology. They will require, at least, different types of application.

Some of the greatest opportunities will be helping schools and districts to identify exactly what the problems are — perhaps the most critical step in the problem-solving process. Defining, implementing, and evaluating outcomes will offer considerable opportunity for school psychologists to identify problems, use low-inference assessment, establish interventions, monitor progress, and determine attainment of the goals/outcomes. The applications may be appropriate at the system and community levels as well as the classroom or student levels. In this chapter, I hope that school psychologists will identify future opportunities and challenges for new roles and realize how the knowledge and skills that they already possess can, with slight redirection, assist schools and districts in facing what some claim to be the most challenging time in educational history.

Why Schools Must Change: A Focus on Outcomes

Since *A Nation at Risk* (1983) was issued, American schools have been under serious scrutiny. Many observers and educators recognize that we are at a defining moment in American education. Poor rankings of American students compared to students of other industrialized nations are often used as evidence that schools are not producing high quality students. Our high dropout rate of 25% or more is cited as additional evidence that schools are failing students. Is it true that our schools are worse today than they used to be?

Some researchers have noted that schools are doing as well as or better than they did in previous decades. Standardized test scores are actually as good as they were in the 1960s, their highest point. While overall Scholastic Aptitude Test (SAT) scores have fallen slightly, a much higher percentage of diverse students now takes the SAT. When scores are analyzed by type of student subgroups, SAT scores have actually increased for every type of subgroup. (See Jaegger, 1992, for an overview of these issues and data.) The dropout rate was approximately 50% in the 1950s, much higher than it is today. In spite of evidence of increased academic success, critics maintain students are less well prepared to take their place in society. The answer to this seeming paradox lies at least partially in the changing requirements of society and the world of work.

Today one can hardly be ignorant of the evidence that the world is changing in fundamental ways and, along with it, our American society. We now refer to the economy in global terms, as we do much of our political life. Diverse cultures of the world are increasingly interdependent. America is especially marked by diverse racial and ethnic groups. Large segments of our youth culture are in turmoil, causing increased violence in schools. Our society is no longer characterized by "traditional" family structures of a working father, stay-at-home mother, and two children. Almost 1/4 of our youth live in single-parent families, and at least 1/5 of children live in poverty. Higher standards of living are no longer assumed for the next generation, and the economic gap between rich and poor seems to be increasing. In short, children coming to schools today are quite different from children of past generations.

Perhaps the most fundamental change is the nature of the economy and the world of work that our children will confront. Even now workplaces are increasingly characterized by high technology. Our era is referred to as the "Information Age." Manufacturing processes often replace human labor with robots or other computerized technology. This kind of economy requires workers who can think, solve problems, and be flexible. Workers are required to work together, often in teams, as well as independently. Drucker (1989) noted that an economy in which knowledge is the true capital and wealth-producing resource will make stringent demands on schools for education performance and accountability.

In this view of a changing society, there is no room for citizens and workers who cannot perform at high levels. Universal literacy that includes higher order skills is required. Thus, while a 25% dropout rate is much better than the 1950s rate, it is not acceptable if all students are to acquire complex knowledge and skills.

Schools today have not changed fundamentally from the way schools have been run for decades and, as such, are not likely to meet the demands of a new economic age. Schools were built to reflect the industrial age, with bureaucratic structures and "assembly line" operations of rigid age or grade promotions, where all students move at the same rate "ready or not." They often reflect "caste" systems where students are slotted into special programs or levels and never get out. Schools typically reflect an emphasis on teaching, not on learning; and the two are not the same.

The last 10 to 15 years of cognitive and educational research have yielded considerable gains in knowledge about how we learn. This new understanding of learning is consistent with the strategies needed to facilitate the types of outcomes deemed necessary for the 21st century society. The American Psychological Association has recently published "Learner-Centered Psychological Principles" (APA, 1992), which all school psychologists should read and study. These principles summarize the best of what is known about learning and reflect the tenets of a view of learning called "constructivism." Practices in schools today generally do not reflect new knowledge about learning.

A new era requires new types of learning and outcomes for all students. And new learnings require new kinds of schools. These new outcomes and how they are learned will drive the reform efforts.

New Types of Outcomes

Inherent in any discussion of restructuring or reinventing schools is the issue of the types of outcomes that schools must address. When outcomes are defined in terms of what is learned, the intended outcomes must be set forth with care (Finn, 1990). While educational reform has frequently focused on traditional norm-referenced test scores, educators and citizens increasingly express a desire for complex cognitive, social, and affective outcomes. Educators are being asked to address significant knowledge, skills, and attributes necessary to prepare students to live in an information society characterized by global economic interdependence, cultural pluralism, rapidly expanding technologies, and decentralized social structures. While the national education goals speak to excellence in traditional subject matter areas, they also reference the need for students to learn to "use their minds well" (Goal 3).

Schlecty (1990) proposes that a new era requires new purposes of schooling. "Knowledge work" should be the focus of schools — using ideas and symbols for some purposeful result. An information-based society relies on knowledge and the ability to put it to work to create, to invent, and to solve problems. The new literacy that requires fundamental and total restructuring of the educational system includes capacities once demanded only of a few: to think critically and creatively, solve problems, exercise judgment, and learn new skills and knowledge throughout a lifetime (Brown, 1991).

During the Bush administration, the U.S. Department of Labor established the Secretary's Commission on Achieving Necessary Skills (SCANS). This group of business and education leaders issued a report, *What Work Requires of Schools* (SCANS, 1991), defining the knowledge, skills, and attributes necessary in high performance workplaces. Under "Foundation Skills" they included ***basic skills*** of reading, writing, arithmetic and mathematics, speaking, and listening. But they also included ***thinking skills*** (ability to learn, reason, think creatively, make decisions, and solve problems), as well as ***personal qualities*** (responsibility, self-esteem, self-management, sociability, and integrity). "Workplace Competencies" were also defined for effective workers. These competencies included ***using resources*** (e.g., allocation of time, money, materials, space, and staff), ***interpersonal skills*** (e.g., work on teams, teach others, serve customers, negotiate, work with people from culturally diverse backgrounds), ***information*** (e.g., acquire and evaluate data, interpret and communicate, use computers to process information), ***systems*** (e.g., understand social, organizational, and technological systems; monitor and correct performance; design and improve systems), and ***technology*** (e.g., select equipment and tools, apply technology to tasks, maintain and troubleshoot equipment).

Clearly, the knowledge and skills reflected by these reports and writers exceed the areas measured by traditional indicators of student success and reflect the need for changes in what and how students are taught. We are not likely to attain these kinds of outcomes in the current schooling paradigm.

The Focus on Outcomes and Learning: A New Schooling Paradigm

The changes cited in the preceding sections are paradigm changes in our world. Systems that met needs in previous decades no longer meet today's problems or opportunities. The concept of paradigm helps to explain the powerful and fundamental shift in understandings, assumptions, and values now emerging in education. Paradigms are the rules and regulations, the stated and unstated assumptions, the "world view" that shape our understanding or ways of viewing something (Kuhn, 1970). Paradigms begin to crumble when they no longer help solve problems.

Paradigm shifts often are not evident to those participating in them. The outcome-focused paradigm has not been linear, but its emergence has been evident in numerous ways. For decades, we have assumed that if we provided enough resources, appropriate strategies, and equality of inputs, we would have equality of outcomes. The Coleman Report of 1966, which asserted that schools could not overcome the socioeconomic status of students, shattered the presumed link between inputs and outputs. Essentially, Coleman maintained that schools could not overcome the effects of social class.

Many researchers felt that Coleman's findings were flawed. They believed that if they could find schools that served all students well, including poor students, they could discover the causes and conditions that led these schools to be effective and, thus, refute Coleman's claims. They defined an "effective school" as one in which academic success could not be predicted by the student's socioeconomic status. Using scores on norm-referenced tests as their measure of academic success, they were able to identify effective schools, as well as correlates that appeared to account for their success. Effective schools, as defined by these researchers, are concerned with how schools can become effective for all learners; equity in excellence is a fundamental premise. Thus, effective-schools research was a major step in linking school process variables (e.g., leadership, instruction, time) to student outcomes and in moving toward an outcomes focus. Other evidence of the shifting paradigm to outcomes can be seen in an increasing number of meta-analysis studies and in Walberg's (1984) productivity research.

Emphasis on site-based management and flexibility in how outcomes are reached is part of the paradigm implying that it is no longer critical *to prescribe how* outcomes are reached, but *whether* outcomes are reached. The establishment of national educational goals by the Governors and the ensuing debate around the issues of a national curriculum, national assessment systems, and new forms of assessment are all a part of the emerging outcomes paradigm. Reform under the existing paradigm has meant trying to do the same things harder, more, or better. While previous reforms have focused on the need for higher standards in terms of traditional course structures, more time for learning, and increased emphasis on the "basics," the outcome paradigm implies

- Graduation requirements based on mastery of essential knowledge and skills rather than a predetermined number of hours in given grades or courses.
- Different mastery rates for different learners across various subjects.
- Multifaceted assessment systems for determining progress (e.g., portfolios, products, demonstrations).
- Transcripts of specific skills rather than courses and grades.

Outcome-based education is increasingly coming to mean a specific paradigm for transforming schools that focuses all of the school's instructional programs and operating structures around attaining important outcomes (Spady, 1992; Spady & Marshall, 1991). Outcome-based educators ask what knowledge, skills, and attributes students will need to work and live in the 21st century, and then redesign curriculum, learning, instruction, and assessment to ensure that these outcomes are reached. In existing schools, time is fixed for all students and achievement (e.g., outcomes) varies across students. In a results-oriented paradigm, outcomes are held constant across students and time for mastery is allowed to vary among students. Clock hours and Carnegie units have little meaning in schools based on performance and mastery.

Whereas the effective-schools movement emphasizes the school as the unit of change and its impact on the student in terms of school goals, outcome-based education starts from the perspective of the student in terms of the outcomes necessary for future success. In this system, everything in schools (e.g., curriculum, instruction, operations, structure) is driven by defined outcomes of significance and existing knowledge of the learning process. It is this understanding that requires fundamental changes in traditional school structures, such as time, credits, graduation units, grade levels, grading practices, student advancement, didactic instruction, and normative assessment.

Skeptics may assert that strategies associated with the outcome-based paradigm have been tried before, including mastery learning, ungraded classes, and continuous progress. If these strategies did not succeed then, why should they do so now? When the research is considered, it becomes clear that many of the previous innovations were, in fact, successful but were unable to be maintained in a system that was fundamentally input-based. A paradigm shift involves changes in every aspect of the framework, not just selected portions as has occurred in the past. In addition, the outcomes perspective is pervasive both inside and outside of education. The push for an outcomes focus derives more from business and the public than from educators. Previous reform efforts typically emanated from educators.

The desperate need for all of our citizens to perform at high levels to be successful in the 21st century and to shape a healthy society is widely recognized. Even noted news columnist, William Raspberry, has written columns that reflect outcome-oriented thinking. In one article (1991a) he questioned the absurdity of an educational system that allows the quality of student work to vary while keeping time fixed. In a second editorial (1991b) he attacked the pervasive academic competition in schools, grading on the curve, and the creation of winners and losers. He asks: "Doesn't it make more sense to make sure that every kid gets a chance — and more than one chance — at academics?"

All of the existing aspects of schooling support a time-based, input paradigm that results in inconsistent outcomes for students. Sorting, tracking, and classifying — system functions currently associated with school psychologists among others — are much less relevant in an outcome-based paradigm. Most aspects of schooling have to change to support a school where intended outcomes for all students drive everything else.

The Outcome Paradigm and School Psychology

School psychologists must reflect on the implications of these new education directions for their practice. A fundamental question is whether our history and training are in conflict with the emerging paradigm of schooling and the assumptions it embodies. While exact origins of school psychology are debated, the psychometric and assessment heritage has permeated our practice for decades. This heritage that evolved from the existing system includes training in ability differences and intelligence testing; assessment practices based on the normal curve; a focus on deficits and remediation; and roles of sorting, tracking, and classifying students for various programs and levels.

The new paradigm replaces an emphasis on ability with an emphasis on effort. It harbors the belief that all children can learn well. It does not assume that all children will learn to the same level or exactly the same things, but recognizes that we often have limited students' choices by labeling them with certain levels of "ability" or fearing that we might expect too much and damage their self-esteem. Cross-cultural studies of perceptions of success in school show that Japanese mothers are more likely to attribute different levels of achievement to effort, whereas American mothers tend to attribute differential success to ability. Our profession's early emphasis on normal distributions, intelligence testing, and placement for special education has likely contributed to the notion that ability is the key trait for success, not effort or hard work.

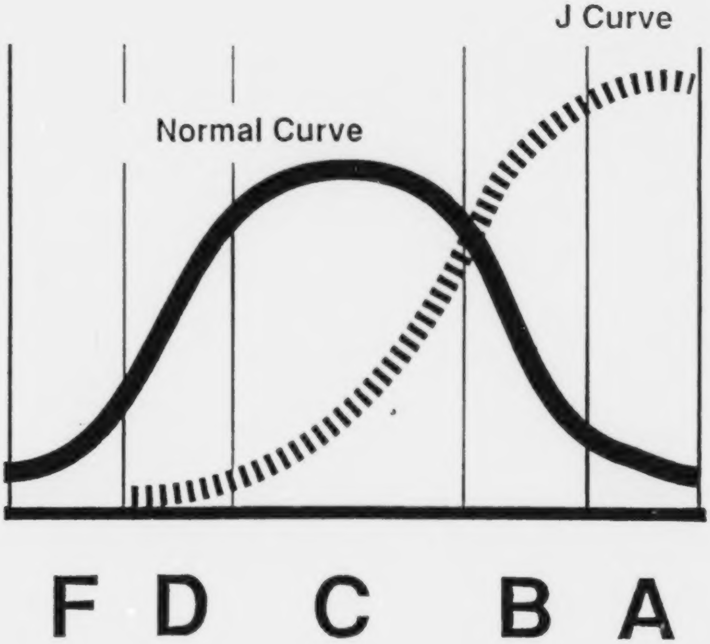
Most educational and psychological assessment has been based on normal distributions. Only recently have we moved into curriculum-based assessments and other low-inference procedures. We have not readily questioned the usefulness of the bell-shaped curve — which assumes as many students fail as succeed, with most being "average." The normal curve is often descriptive, but we have used it in our profession and education as "prescriptive" and "predictive." Larry Lezotte, noted effective-schools researcher, has observed that we could attain a normal curve of achievement without schools; it would merely reflect the population performance without intervention. If schools really are effective, they should not yield a bell curve of achievement (Lezotte, 1990). We should begin to see a "J-Curve," where most students achieve what schools intend that they learn. Figure 1 illustrates the difference in the theoretical distributions of the normal and J-curves. It should be noted that the J-curve can be obtained by setting low standards. But in schools that are restructuring around high-level outcomes for all students, the intent is that most students will attain satisfactory performance on these challenging outcomes (e.g., grade C or better).

Assessment in the Outcome-Based Paradigm: An Example.

Because assessment has always been fundamental to the school psychologist's role, examining that role in outcome-based education may be useful. Figure 2 illustrates assessment assumptions and practices along the dimension of "test inference." Inference refers to the extent to which the sample of behavior assessed by a particular instrument matches the behavior of concern in real life. Thus, projective personality assessments and intelligence tests may be referred to as "high inference," requiring a fair amount of interpretation between the sample of behaviors on the instrument itself as compared to the observation of those traits in daily life. "Low-inference" procedures, on the other hand, more closely approximate the actual behaviors of interest. In communicating with teachers, high-inference assessment might be referred to as indirect measurement and low-inference assessment as direct measurement.

A number of assessment dimensions, as well as elements or characteristics of each dimension, can be

FIGURE 1. Normal and J-curve expectations of success.



plotted along this inference continuum. While there is no exact point on the inference continuum where characteristics of each dimension fall, the location should be considered approximate and relative to other assessment characteristics on the same continuum. For example, the "domains of assessment" (the first dimension) included in high inference/indirect assessment typically include psychological traits, such as personality characteristics or intelligence. As we move along the continuum toward low inference/direct assessment, we are more likely to measure actual knowledge and, ultimately, skills. Similarly, the "types of assessments" (second dimension) associated with these domains begin with norm-referenced assessment (high inference) and move sequentially through criterion-referenced assessment, curriculum-based assessment, portfolios, and performances or demonstrations in moving toward lower inference procedures.

Typically, high-inference procedures occur in "decontextualized" or artificial settings. They frequently focus on discrete (some say trivial) skills or behaviors and are designed to sort, track, and classify. Thus, they require forced or high variance, resulting in normal distributions. Low-inference procedures are measured "in context" or in authentic (real-life) settings. They focus on culminating skills and are concerned with proficiency and instruction. As such, they reflect low variance and seek to attain a J-curve, where most students are mastering culminating skills of significance.

Thus, the types of assessment built around norm-referenced, high-inference procedures typically focus on comparing students to each other. Low-inference procedures are more likely to compare individual performance to a target set of criteria. These criteria are set forth in advance so that students are "in on it" from the beginning. The focus is on mastery, not mystery, learning.

The depiction in Figure 2 is not meant to ascribe value only to high- or to low-inference assessment. Both types of assessment have a purpose and appropriate uses. However, assessment in the traditional schooling paradigm has been characterized by high to mid-level inference strategies, with the primary purposes of sorting and classifying students. Although there are examples to the contrary, this paradigm is where school psychology currently resides in the main. Increasingly, use of norm-referenced assessment to determine student achievement or to predict future achievement is under serious scrutiny.

Low-inference assessment is integral to an outcome-based paradigm of schooling. The focus is demonstrated mastery for most students; thus, low variance in scores is typical. If school psychologists are locked into a belief system holding that ability among students is normally distributed (therefore achievement among students must be normally dis-

FIGURE 2. Implications of high- versus low-inference assessment.

J - Curve

tributed), and students at the lower end of that curve cannot learn significant outcomes for the 21st century, then we will not be very useful to schools of the future. Even more germane to the point of this book, low-inference procedures are essential to effective problem-solving for students, classrooms, and systems. Understanding low-inference assessment in the context of schools that emphasize higher order outcomes for all students is essential.

The opportunities for school psychologists in an outcome-based paradigm of schooling are numerous. But we will need to reconsider our historical training, assumptions, and beliefs if we are to mesh with a system intent on all students learning successfully and attaining knowledge and skills necessary to live and work in the 21st century.

BASIC CONSIDERATIONS

Knowledge and Skills for a Shifting Paradigm

Fundamental to moving beyond our historical beginnings is a shift from a mental health and deficit model to one of educational attainment and development for all students, from clinical to instructional terminology, and from a focus on the individual to a focus on increased systems interventions (Cobb, 1990). If we are to focus on educational attainment for all, school psychologists must

- Understand low-inference assessment procedures and move to assessment that facilitates achievement and measures accountability in terms of attained outcomes.
- Move away from comparing, sorting, and classifying students for programs defined by labels rather than by instructional needs.
- Be current with the research about learning and how higher order skills are acquired.

If students are to be proficient at understanding systems (SCANS, 1991), school psychologists can be among the most useful personnel in education to help students develop those skills. Of course, school psychologists have to be taught to think in systems terms as well.

Many skills that school psychologists currently have will be useful in an outcome-based paradigm of schooling. However, the reorientation of some of those skills (e.g., assessment) as well as the acquisition of new types of skills will be required in order for school psychologists to be relevant to mainstream instruction and reform in American schools of the future. A few areas of relevant knowledge and skills to be acquired by school psychologists, as well as incorporated into preservice training programs, are suggested here.

Understanding the future and work force needs. School psychologists must attend to discussions about the future and requirements of citizens in the 21st century. We must be able to help define the types of outcomes that will be relevant for student success in work and life. We must, at the very least, attend to news articles about such things as the changing world of work and new systems for society's challenges. More formal reading in these areas, including membership in organizations like the World Futures Society, may also be helpful. An extension of these skills would include vision-driven strategic planning, where school district plans are shaped by a vision of where they want to be in the future, what they will look like, and what external forces will impact them.

Systems theory and operation. Many school psychologists already study systems theory, but all need to do so. A systems view is useful because it

1. Helps examine external influences from other systems.

2. Highlights the impact of our "outputs" and services.

3. Helps us see that we are not helpless but can behave in alternative ways toward external influences.

4. Emphasizes that in order to change any system component in a substantive way, the entire system must be considered and possibly altered (Katz & Kahn, 1978).

Interestingly, the SCANS report identifies the understanding of how systems operate as a basic outcome to be required for all students. Psychologists need to know how systems operate and can be changed so that they can both effect change in the public schools and help ensure that students understand and can improve or design systems. (See the chapter in this book by Michael Curtis on systems consultation.)

Organizational change and group process. Related to systems theory, knowledge of organizational change and group process skills are essential to implement new schooling paradigms, empower all staff, and create effective organizational structures. Understanding and impacting organizational culture (e.g., roles, rules, relationships), reshaping organizational structures, understanding the change process, and facilitating work and decision groups in schools are all essential roles in the emerging school restructuring paradigm. These roles are particularly appropriate for school psychologists.

Constructivist principles of learning. It is critical that school psychologists are current in their understandings about how learning occurs. Many school psychologists have been well-schooled in a behavioral model of learning. While there are many useful behavioral principles, the behavioral view of learning that focuses on strengthening bonds between stimulus and response, breaking tasks into component parts, getting the "right" answer, and repetitive training is rapidly becoming outmoded. Learning has been studied in laboratory (artificial) settings, and cognitive psychologists assumed that knowledge and skills could be acquired independently of context (Berryman, 1991).

Today, the predominant view of learning among cognitive and educational psychologists is called "constructivism." Learning is viewed as a goal-directed process, where meaning is constructed from both information and experience. Learners construct representations of knowledge that make sense to them; they associate and connect new information with what they already know. Constructivist research contains important implications for how to teach. For example, it is not necessary that students learn basic skills before learning problem-solving skills. These skills are not necessarily sequential but rather are mutually reinforcing. Instruction should be reoriented away from mere mastery of facts and information and toward the recognition and solving of complex problems. Real "know-how" cannot be taught in isolation; students need practice in applying these skills in real-life contexts.

The American Psychological Association has produced "Learner-Centered Psychological Principles: Guidelines for School Redesign and Reform" (APA, 1992). These principles synthesize state-of-the-art research and knowledge about learning, including elements of the brief review presented here. The learner-centered principles address metacognitive and cognitive factors, affective factors, developmental factors, social factors, and individual differences. Implications for aspects of school redesign include instruction, curriculum, assessment, instructional management, teacher education, parent and community involvement, and policies. All school psychologists should read and study these principles. The principles reflect ways that school psychologists can be part of schools of the future, help schools set significant outcomes for students, develop classrooms and school environments to achieve these significant outcomes, and determine if the outcomes have been attained (i.e., problem-solving for school reform).

Research on instructional and school practices that improve outcomes. The success of school psychology in 21st-century schools requires that their work have greater relevance to the instructional elements of schooling, including curriculum, teaching processes, and the learning environment. To be effective problem-solvers at the individual student, classroom, and district levels, school psychologists must rely on an empirical base of knowledge about what works to improve achievement and other student outcomes. There is a growing base of research on effective classroom and school-level practices.

Constructivism, for example, supports the belief that curiosity, creativity, and higher order thinking are stimulated by learning tasks that are challenging, relevant, authentic, and novel. Learning and self-esteem are enhanced by interacting with others in flexible, respectful, and caring instructional settings and relationships (APA, 1992). Instruction that is consistent with constructivism and higher order outcomes requires that students be active rather than passive learners. Teachers are facilitators of learning rather than dispensers of information. While there is a place for didactic instruction, classrooms must facilitate hands-on activities, interaction, and collaboration. Teachers help students make interdisciplinary connections and provide a setting for risk-taking, experimentation, and active manipulation of physical structures and models. Learning units may be more extended and integrated through themes or projects.

Other effective practices include, to name a few, heterogeneous classes (vs. between-class ability grouping), functional grouping and regrouping, reduced grade retention, cooperative learning strategies, peer helping, integrated instruction, accelerated learning, and student-led conferences. Teachers will need to know how to use grouping and regrouping strategies in the classroom effectively. Cooperative learning, peer helping, and student-led conferences are appropriate strategies for classrooms where students are active and responsible learners. School psychologists should be familiar with various instructional strategies to help teachers problem solve for effective instruction of individuals and groups of students.

Research suggests the effectiveness of a number of school-level programs. The Stanford Accelerated Schools Project (Levin, 1991) is based on the premise that at-risk students must learn at a faster rate than more advantaged students — not at a slower, remedial rate that drags them down further. The intent is to bring them into the mainstream at grade level by the end of elementary school. The School Development Program (Comer, 1988) incorporates the elements of effective schools and builds on the needs of the whole child, including other community agencies and parents in the educational planning for children. The Coalition of Essential Schools (Sizer, 1992) emphasizes the need for rigor, disciplined habits of mind, integrated instruction, and problem solving at the high-school level. Success for All (Madden, Slavin, Karweit, Lawrence, & Wasik, 1991) uses a combination of strategies (e.g., cooperative learning, whole language) to bring the achievement of highly disadvantaged students up to grade level. While the school psychology literature may include some important information in these areas, school psychologists likely will need to refer to educational practice and research journals to acquire information particularly useful to school personnel and reform.

A key contribution of school psychologists is their skill in understanding the research and translating it for application and practice. Suggesting policy, program, and instructional implications of the research is one way psychologists can build the research base into teaching and program development in schools.

Authentic assessment strategies. Assessment has moved to center stage in the national debate on educational reform. High-stakes assessment has traditionally been defined by normed-referenced, standardized achievement tests that focus on discrete knowledge in given subject areas and that compare students to each other. New assessment practices that reflect the type of learning and instruction described previously are increasingly at the center of the discussion. These assessments are often referred to as "authentic" or based on real-world performances and tasks. Sometimes the terms "authentic" and "performance-based" are used interchangeably, because real life expectations require some demonstration of knowledge and skills. Compared to conventional assessments, new assessment practices

- Are ongoing and cumulative versus annual.
- Use open-ended versus multiple-choice formats.
- Draw upon a variety of settings versus a single setting.
- Are performance based versus paper and pencil.
- Are criterion-referenced versus norm-referenced.
- Are teacher mediated versus teacher proof.

Authentic tasks are becoming important aspects of instruction and assessment. Assessment in this paradigm is designed to be an integral part of instruction and is often not distinguished from it. Thus, teachers need considerable assistance in understanding how classroom instruction can be reliably and validly assessed. Authentic assessment in the classroom involves worthy tasks from the real world that require students to apply their knowledge and skills. Authentic assessment engages students, involves self-assessment and frequently peer assessment, and requires preset criteria to let students know "up front" what constitutes acceptable and exemplary performances. Students have an active role in determining the target learning criteria and learn to reliably assess the performance of self and peers. Examples of performance assessments include direct writing assessments, extended projects, presentations, investigations, open-ended questions, debates, and experiments. To be maximally helpful to teachers, school psychologists should expand their knowledge to include these types of assessments and skills.

The use of authentic assessments at district, state, or national levels for high-stakes decisions is still being debated. Issues of reliability and validity are central to the national debate. Some educational psychologists believe that new forms of validity will become important. Whether results from a single performance task can be generalized to the entire domain of concern is also questioned. Shavelson, Gao, and Baxter (1993) found that large numbers of tasks are necessary to get a generalizable measure of performance, regardless of the subject matter (math or science), domain (education or job performance), or level of analysis (individual or school). For example, they estimate that approximately 10 performance tasks in science would be necessary to get a reliable estimate of a child's understanding of science in general. Obviously, performance assessment is time-consuming and expensive, especially for decisions outside of the classroom as Vermont recently discovered when they used portfolios as part of their statewide assessment with discouraging results. Although reliability between raters was acceptable for groups of students, it was extremely low for individual student scores. Nevertheless, districts, states, and national groups are pursuing the possibilities of performance or authentic assessment for large-scale purposes. School psychologists must be informed about and participate in these debates to assist districts in developing appropriate and accurate assessments.

Understanding the "quality" issue. After being a pivotal issue driving many business reforms of the 1980s, the notion of "high quality" performance is infusing education. Total Quality concepts such as worker-level decision making, continuous improvement, and self-assessment based on clear criteria are being used by many teachers and districts. Teachers work with their students to establish the criteria or rubrics for quality work in the classroom. Likewise, principals work with teachers to determine criteria for quality teacher performance. The student and staff outcomes established by many districts and states often include the concept of quality work. School psychologists should have a basic understanding of Total Quality concepts as described by Deming (1986) and others to assist schools and districts in implementing new types of outcomes, as well as in carrying out restructuring efforts.

BEST PRACTICES

With a slight reshaping of the knowledge and skill base, school psychologists can be some of the best-trained professionals in schools to help teachers, schools, and districts implement and evaluate new types of educational outcomes. Opportunities for problem-solving roles exist at the community, system, school, classroom, and individual-student levels.

System- and Community-Level Roles

As school districts consider the desired types of student and staff outcomes and results and the types of restructuring changes necessary to achieve them, they often engage in vision-driven strategic planning. School psychologists can be instrumental in developing a constructive process for strategic planning, as well as the transition processes necessary to shift the district's focus and priorities. The existing problems and need for change must be clearly defined by staff and the community. Strategic planning involves assessment of the environment (often called environmental scanning), as well as the strengths and needs of the organization. From a problem-solving perspective, the steps to effect the desired changes are system "interventions." Mechanisms for continuous monitoring of progress toward attainment of desired goals is essential as are knowledge of systems, organizational change, and group processes if school psychologists are to help lead systems through this type of fundamental change.

Districts also need assistance in determining the types of outcomes that will drive their restructuring and instructional efforts. Facilitating the development of outcomes that meet the needs of living and working in the 21st century and that are based on what we know about learning is a critical role for school psychologists. Outcomes usually include knowledge, skills, and attributes desired for all students. Coalitions and consensus in the community around these outcomes, including involvement of citizens, parents, and students in the development process, is essential to the attainment of designated outcomes. If school psychologists understand the future work force and citizenship needs, current knowledge about learning, and group process skills, they will be able to be key players in this process.

As school psychologists work with parents around individual student problems or needs, they can help parents understand the outcomes expected of their children and ways that parents can further attain those outcomes. By linking specific interventions to district-level outcomes, school psychologists will help reinforce the importance of the outcomes and more likely ensure that all students attain them.

Developing and selecting performance-based assessments for district accountability systems that measure new types of outcomes also provides an important role for school psychologists. Their understanding of the issues involved in moving from sole reliance on norm-referenced achievement tests to performance assessments and other measures of outcomes is critical. While most educators maintain that instruction should drive assessment, in fact assessment often shapes the nature of instruction. In developing district-wide assessment procedures, schools must consider the various purposes for which assessment data are needed, as well as the impact of the assessment system on teaching and learning. A combination of low-to-moderate-inference assessments may be useful, and psychologists will need to help schools match assessments to purposes in meaningful ways. Specifically, psychologists might

- Study existing assessments.
- Assess gaps in what is needed to move in desired directions.
- Lead groups through a study of alternative assessments.
- Assist in development and/or selection of system-level assessments.
- Link results of assessments to district goals and outcomes.
- Evaluate the appropriateness and use of district accountability systems. (See Elliott, 1992 for a more complete description of one school psychologist's role in district-level assessment.)

School- and Classroom-Level Roles

Learning to teach to new types of outcomes, employing appropriate instructional strategies, working with groups in classrooms, and applying authentic assessments will be daunting challenges for most teachers and principals. Educators often cite the belief that all students can learn well, but real application of that belief requires changes in how students are taught, grouped, graded, and advanced. School psychologists can be valuable contributors to staff development or "capacity building" for teachers. Areas of training might include current principles of learning and their classroom applications, team work, effective instructional strategies, and strategies to address skills and attributes as well as content knowledge, and classroom assessment.

Collaborating with teachers to plan and implement new instructional practices in the classroom will require school psychologists to use careful problem-solving strategies. For example, the teacher's state of readiness and real goals (problem definition) should be determined. Strategies currently in use and the teacher's level of knowledge and skills regarding new instructional strategies that reflect constructivist learning principles and new types of outcomes also should be assessed. Specific measurable goals for implementation of new strategies should be established. When appropriate, the psychologist should work closely with the teacher as new strategies are employed, providing feedback, coaching, modeling, or other support interventions.

Even consultation with teachers and other staff regarding individual students can be focused around the district's outcomes. If instruction and assessment are aligned with culminating student outcomes, then everything — including consultation goals — should be designed to help students reach these exit or culminating outcomes. Because many districts include outcomes that reflect desired attributes (e.g., responsibility, self-management, perseverance), even interventions for behavioral problems should be viewed in the light of facilitating district-level outcomes for all students.

"All" means all. The status of students with disabilities in outcome-based education is an important issue. When we say outcomes are to be specified for *all* students, do we mean to include students who are mentally or learning disabled or otherwise impaired? Many educators believe that exit outcomes or goals should be stated so that *all* students are included. An outcome that describes a "quality worker" or "contributing citizen" can apply to any student regardless of mental or emotional status. The specific levels of outcomes, the nature of instruction, and ways that outcomes are assessed may vary for students with disabilities. However, if culminating outcomes are stated in terms of subject matter content (e.g., algebra), then *all* will not mean all. In the state of Kentucky, exit outcomes are intended for all students. A statewide portfolio assessment system has been developed to assess severely disabled students on these outcomes at levels appropriate to their individual goals and abilities. Nevertheless, these individual goals are driven by the statewide exit outcomes. It should be noted that Kentucky expects the majority of students with disabilities to participate in the regular statewide assessment procedures.

It will be imperative that school psychologists guard against the excuse that these students are disabled and should not be pushed too hard. Helping to determine high-level *yet reachable* outcomes for students with disabilities may be one of the most difficult and crucial roles that school psychologists can play. This role will include understanding how exit outcomes apply to these students, using low-inference procedures to determine their status relative to these outcomes, developing instructional and behavioral strategies and interventions that facilitate learning these outcomes, and measuring student progress toward achieving these outcomes. Assisting school staff with inclusion practices and consulting for student success in regular classes will also be important. Perhaps even more critical will be helping more people believe that students with disabilities can attain high-level outcomes.

A Final Note

A single school psychologist probably will not perform all of the roles cited in this chapter. However, the opportunities to develop, implement, and evaluate high-level outcomes for all students exist in a myriad of ways. An attempt could be made within a district staff of school psychologists or within a regional consortium of school psychologists to provide many or most of the functions and roles suggested here, from those at the individual-student level to system level.

The opportunities described here are not necessarily all inclusive. For example, there are five trained school psychologists, including this author, who currently are employed in the North Carolina Department of Public Instruction. Only one of those is designated as the "school psychology" consultant. A second psychologist came to the Department in the personnel area that developed professional performance appraisal and career ladder systems. He later became chief consultant of the Student Services Team in the High School Division. The other three of us work in the Division of Innovation and Development Services, which I direct. Two of my three Development Unit staff are the other two school psychologists. They were interviewed and selected by teams; I did not make the decision alone to hire them. They each rose to the top of fairly large applicant pools, as did the psychologist in personnel services, because of their apparent understanding of systems, writing and presentation skills, collaboration skills, ability to understand research and translate it into implications for practice, and ability to contribute to our program evaluation efforts. The training of school psychologists, especially with some additions and shifts in focus, prepare them as well as any other professional to assist in defining and reaching important educational goals.

CONCLUSION

Schools in America are attempting more fundamental changes than ever in their history. Public demands for high performance are coming at a time when schools have the most diverse population of students in their history. Although schools appear to be doing as well as ever on traditional outcomes, the demand for graduates with new types of knowledge, skills, and attributes is driving the need for a new type of schooling. The challenges are formidable, but the opportunities are considerable for school psychology. The need for problem-solving skills will be greater than ever. School psychologists, mired in the paradigm of norm-referenced thinking, will not be able to seize these opportunities. We must operate within a paradigm driven by high-level outcomes for all students, a belief that all students can learn well, and the understanding that schools, in fact, control the conditions of success for students.

AUTHOR NOTE

I am particularly thankful to Delores Brewer for several substantive and editing suggestions, as well as to Bobbye Draughon and Judy White for their helpful editing comments. Delores Brewer and Judy White are both school psychologists in the Division of Innovation and Development Services. Bobbye Draughon is the chief consultant in the Division.

ANNOTATED BIBLIOGRAPHY

American Psychological Association. (1992, September). Learner-centered psychological principles: Guidelines for school redesign and reform (draft). *Communiqué*, pp. 15–18.
These principles summarize psychological research and knowledge about learning and the implications for schools. They address metacognitive and cognitive factors, social factors, affective factors, developmental factors, and individual differences. Implications for instruction, curriculum, assessment, teacher education, and parent and community involvement are listed.

Brandt, R. S. (Ed.). (1993). The challenge of higher standards. *Educational Leadership, 50*(5).
With the current efforts underway to establish national standards in subject areas, this journal issue examines the potential impact, promise, and problems of such standards. In the search for new types of outcomes, school psychologists should be part of these issues and debates.

Elliott, S. N. (1992, October). Authentic assessment: A case report of system change. *Communiqué*, pp. 4–5.
Dr. Elliott describes how he became involved as a parent and school psychology trainer in helping his local school district explore and begin to develop evaluation and authentic assessment strategies for student outcomes, programs, and services. He explains the strategic planning process and delineates possible roles for school psychologists in the use of alternative assessment methods.

Spady, W. G. (1992, March). It's time to take a close look at outcome-based education. *Communiqué*, pp. 16–18.
Spady defines the meaning of "outcome-based" education (OBE), describes the evolution of the concept, and defines three types of OBE: traditional, transitional, and transformational. He clearly defines the implications for OBE, regardless of the type implemented, for our educational system.

Secretary's Commission on Achieving Necessary Skills. (1991, June). *What work requires of schools: A SCANS report for America 2000.* Washington, DC: U.S. Department of Labor.
This report from a Commission composed of educators, business representatives, and citizens delineates foundation skills and broad competencies necessary for students to work successfully in the 21st century. It also compares schools of today with those of tomorrow necessary to achieve these skills.

> (Evans-Pritchard, 1962)

Before examining the role and impact of culture upon the practice of school psychology, and in the educational lives of children served by school psychologists, it is best if the reader understands how culture has been conceptualized. This chapter first presents a selected review of literature on culture, followed by perspectives of how culture can influence various aspects of a child's life and his or her educational experiences (identity, achievement, communication, and family). The chapter concludes with some discussion about how culture can be considered when attempting to understand and work with children from educational settings in the areas of assessment, intervention, or consultation.

For this chapter culture is defined as the varied patterns of living, traditions, and attitudes possessed by individuals. These patterns of living, traditions, or attitudes are developed out of the person's specific place of origin, and subsequent caste, yet are influenced by transmitted messages from parents/community. By defining culture in this way, one looks at groups such as women and people of color as cultural groups. To assist in this examination of culture, it might help to use a person by environment (PXE) interaction perspective (Lewin, 1935). From this frame of reference, the person's behavior must be evaluated within the setting/social context from which it originates. Lewin's view advocated the understanding of a person's behavior and perceptions by establishing a "definite form of structure in a definite sort of environment" (p. 43). That is, one must develop a view of both the individual-level and environmental-level (culture) of the "organism."

During the course of this chapter, as cultural contexts are being examined, the reader may notice statements about various environmental experiences attributed to groups of people. That is because being a part of a culture often means sharing certain experiences and possibly ways of being. These generalized notions are somewhat distinct from traditional stereotypes in that stereotypes are behaviors assumed to be unilaterally true for a person or a group of persons, without observation or experience of that person(s). In addition, it is often assumed that groups of people are homogeneous, or without variation within their cultural group. It is not the intent of the writer to perpetuate that notion in this chapter. Researchers and practitioners in education and psychology alike must constantly guard against making such assumptions. Generalized statements in this chapter, however, are statements taken from research or theoretical notions in an attempt to examine cultural issues from the perspective of the person-by-environment interaction theory.

A Review of Related Literature

An examination of social science literature illuminates the running dialogue about "what is culture?" Immediate culture is often considered to be the child's home and local community. This perspective seems to perceive culture as connected with values and norms inherent within the environment of socialization. Frisby (1992) presents and critiques six "connotative meanings" for culture. His presentation points out the range of definitions of culture from a pattern of living, customs, and traditions to race consciousness to a difference in outer appearance. Geertz (1973) defines culture as an "historically transmitted pattern of meaning" (p. 89) in a symbolic format by which humans perpetuate and communicate knowledge and attitudes. Another definition offered by Gordon and Armour-Thomas (1991) defines culture as "status phenomenon" (p. 87). This perspective enables one to determine the societal status of the individual along with the privileges available to him or her. The definition of culture that a person uses often guides his or her own mode of research and subsequent practices in social science and education as well as influences the assessment and consultative practices of school psychology.

In the United States, national identity has been filtered through our ethnic origin because cultural values and behavioral norms were transformed here. Race (a unique variable of ethnicity) differentiates people by their physical appearance. It is used as a social identifier in the United States of persons who have an African, Asian, Indian, or Hispanic as opposed to Caucasian origin through at least one ancestor. There are not always, however, one-to-one correspondence between ethnic origin and cultural practices. The connection between ethnicity and culture therefore is partly understood by examining acculturation.

The degree of acculturation has a strong impact on the adherence to original cultural norms (Ogbu, 1978). Acculturation is the extent to which values connected with one's culture of origin have been set aside or changed for the adoption of the dominant culture. An illustration of this phenomenon could be seen among those African Americans who may have adopted "American or European American" traditions above African or in concert with those traditions from some part of Africa. Malgady, Rogler, and Costantino (1987) describe the distinctions between acculturated Hispanics who accept and identify with Anglo interactive styles or conventions versus those who adhere to Hispanic cultural ways of interacting. They cite examples such as the use of English versus Spanish, thinking in the "here and now" versus having a "teleological" orientation. Another factor influencing acculturation level is socioeconomic status. Often the groups at low socioeconomic levels are those least acculturated into majority culture (Ogbu, 1978).

By bringing the issue of culture, acculturation, and ethnicity into the discussions about the school environment, cultural diversity has become one of several central issues for the educational system. Perhaps the first step in the process of examining this issue involves seeing culture as connected with traditions and attitudes held by the individual. The second step involves viewing culture in conjunction with place of origin (country, region) or the conditions under which a cultural group existed in this country. Third, the attitudinal messages adopted from parents and community, and the subsequent level of acculturation, is important to consider. It is the parental or community group message that often contains values/attitudes different from those of the psychologist and other persons within the school environment. For example, a Japanese American child will bring cultural attributes to the school setting if his or her parents and community stress those traditions and values specific to his or her region or continental place of origin (Kitano & Kikumura, 1976). So if the individual's view of competition is inconsistent with the use of competition in school, understanding these disparate views would be helpful for the child and those working with him or her. Understanding that, depending upon level of acculturation, this child might not make direct eye contact and may be very compliant will help both teacher and school psychologist work more effectively with the child. Borrowing once again from Lewin's perspective, it is the understanding of the dynamics between the individual and environment that becomes a key factor in this situation (see Figure 1). It is important to recognize the individual characters in concert with the influence of socialization within a family, cultural group, and a socioeconomic group, and impacted by an education system housed within a social mileu.

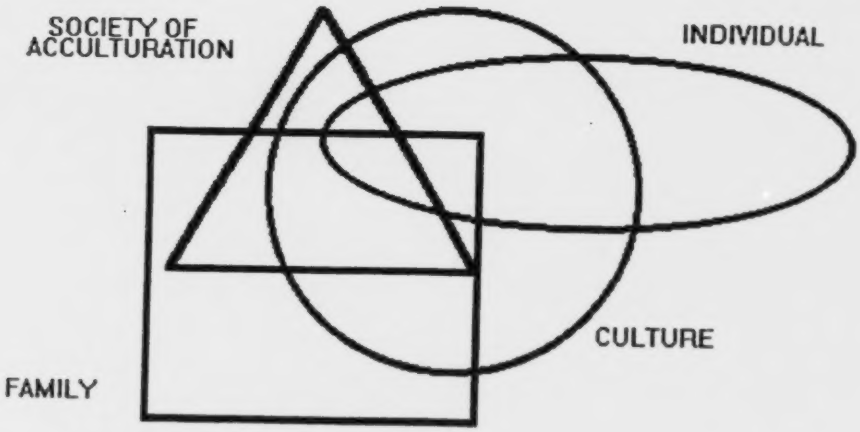
Even though the school environment typically creates an Anglo or European American atmosphere (competition, individualism, uniformity, materialism), the school environment, as a salient context for social exposure, should be charged with the responsibility of facilitating awareness of the contents of diverse "cultural systems" (Boykin, 1986; Ogbu, 1988).

Within the school setting, some school psychologists already serve a significant number of learners from culturally diverse backgrounds. According to the Department of Education's *Digest of Education Statistics* (National Center for Education Statistics, Office of Education and Improvement, 1993) some areas of New York, Florida, and California already have between 30% and 80% "minority" students in the schools. That number will increase dramatically over the next 10 years until there is a majority of non-white or non-European Americans within many school systems (Henry, 1990). It is imperative therefore to be mindful of what role culture plays in the lives of learners. School psychologists are not always adequately introduced to theory about the complexities of culture nor is there adequate time spent considering the impact of culture upon practice (Barona, de Barona, Flores, & Gutierrez, 1990; Rogers, Ponterotto, Conoley, & Wiese, 1992). In addition to general lack of information or exposure, some school psychologists have not clarified their thinking about the construct of cultural diversity. In this next section, basic issues are presented that may aid in the process of rethinking and solidifying notions around questions of cultural influences on identity, achievement, communication, community, and family systems.

Impact of Culture on Sense of Self

Often an area of interest in the research on "minority" children in schools are the factors that contribute to their sense of self. Research about the impact of same-sex and/or same-race schools generally points toward the enhanced sense of esteem, resulting from experiences that students have as they ma-

FIGURE 1.



triculate within these culturally homogeneous settings as opposed to heterogeneous ones (Collison, 1991; Lee & Byrk, 1986). Students that attend same-sex or same-race schools tend to have higher levels of esteem and/or different school experiences (Sadker & Sadker, 1994). For example, in heterogeneous classes, girls are not asked as many probing questions during classroom discussions as boys and teacher wait-time differs between girls and boys. Also, disproportionate numbers of African American children experience pedagogical strategies that may be inconsistent with their optimum mode of learning (Allen & Boykin, 1992; Sadker & Sadker, 1994). However, despite the benefits of homogeneous settings, questions are raised about hidden disadvantages such as isolating children from settings that mirror the real world and evaluating whether homogeneous settings can truly be equal.

The issue of racial or gender identity development adds yet another factor inherent in the development of all culturally diverse youth (White & Parham, 1990). The struggle to balance culture of origin with the exposure to European American views or male cultural views plays a key role in the development and subsequent behavior of culturally diverse youth. Psychologists working with culturally diverse youth may need to understand their exposure to and struggle with these divergent cultural influences in order to understand the youth's need to "hold on" to role models from their culture of origin, to celebrate their cultural elements, and to affirm self. Cross (1991) and Helms (1985) have proposed that "minorities" move through stages of identity formation similar to Erikson's (1963) model of psychosocial development. Through these stages, youth will move from rejecting one's culture and often having a preference for the dominant culture, to rejecting the dominant culture, to ultimately internalizing cultural influences and striking a balance between the culture of origin and the acquired culture. Recognizing this model of identity development might prove of value to the school psychologist helping culturally diverse youth with their socialization process.

Impact of Culture on Academic Achievement

A second area to consider in this examination of culture is school performance and social behaviors (interpersonal relationships) that often influence academic achievement. When considering the impact of culture upon the student, the psychologist may want to consider racial-social-economic attributes to gain a full understanding of how culture impacts academic performance and subsequent behaviors surrounding school life. To foster a clearer understanding of this connection, the work of Ogbu (1988, 1992), Boykin (1986), Allen and Boykin (1992), Sue and Okazaki (1990), Gopaul-McNicol (1992a), Asante (1987), and Hale-Benson (1986) is recommended. These writers discuss the connection between academic pursuits and the influence of cultural frames. Such connections can be found in Ogbu's (1992) approach of conceptualizing African Americans as a caste-like minority and trying to recognize the impact of involuntary citizenship in America, acquisition of one's status by birth, limited access to social goods because of group membership, and collective institutional discrimination. A focus on Native Americans and their life-long struggles for consideration as a people and their historical segregation might lead to a fuller understanding of the impact of these experiences upon the academic performance as well as acculturation of youths from these groups. Cultural elements greatly influence educational experience, self-perception, perception of the educational system and its members (including that of the psychologist), and subsequent achievement.

By examining another cultural frame, discrimination, one may see another connection to academic achievement. With systemic discrimination sometimes comes a disillusionment which often leads to anger and/or blaming of that system. Sometimes children of various cultures harbor unacknowledged anger toward the system that they perceive to have established barriers and lessened expectations for them. Others do not perceive barriers or discrimination with the social system but rather many opportunities afforded to them. They take these opportunities and through individual effort and social support turn them into successes. Responses to this situation are as varied as the perceptions of it: from dropping out or lashing out (Council of the Great City Schools, 1987), to proactive and creative strategies for systemic change, to demonstrating exceptional academic success in the face of barriers (Ogbu, 1992).

Another example of the impact of culture on academic experience is the low rate of minority children attending preschool. The *Digest of Education Statistics* (National Center for Education Statistics, Office of Education and Improvement, 1993) states that 37% of African American children and 27% of Hispanic American children 3 to 4 years of age attended any private or public preschool in 1992. This means that in many cases early cognitive learning and cultural indoctrination occur at home. Because of this "at-home" preschool education these children sometimes come to the European-American K–8 system with a culture-specific set of learning styles, learning goals, and expectations. Negotiating the new system on their own can be challenging. One useful strength comes from this experience, however: the valuing of education that most people of color possess (McAdoo, 1993). This value and others are shared by many people and it could be that these shared values can serve as a foundation upon which to build an academic experience where all can succeed. Using the person-by-environment perspective could help in identifying the elements both brought by the individual and existing within the academic environment that together contribute to potential success.

Impact of Culture on Communication

Within each culture exists various modes of communication. One difference that may manifest itself is the varying forms of direct and indirect communication used by different cultures. For some European-Americans and men, indirect communication is used as a way to make requests. For example, an European American teacher saying "it is chilly in here" could be a way of asking someone to close the window. Some children of color may interpret this statement as directly expressing that the teacher is cold and not see it as a request for them to close the window. This scenario could result in the teacher's perceiving the child as unresponsive or even defiant. Some people of color use direct forms of communication even though the mode of delivery varies. For many Asians, Hispanics, and Native Americans, direct eye contact between adult and child could be a sign of disrespect, while a direct message is being delivered. It may not be unusual for a child socialized within these cultures to look down while communicating with an authority figure.

Disclosure during communication also often varies across cultures. African Americans often prefer to turn to indigenous support systems (e.g., family, friends, minister) when disclosing personal issues or seeking support (Hines & Boyd-Franklin, 1982; Neighbors & Jackson, 1984). This same preference was observed in a study of native Puerto Ricans and first generation Puerto Ricans socialized in this country (Zayas, 1988). Some Appalachians also divulge very little outside of the family circle, while other European American subgroups turn more readily to "professionals" and others outside of their immediate circle for contact or assistance.

In addition to the mode of communication, style could also be an issue. Dialect and bilingualism, as influenced by culture of origin, often affect ease of communication and subsequent learning. In addition, schools expect, advocate, and value the use of "standard English" while some minorities use both "standard English" and dialects or languages with which they identify. Some studies (Hudson, 1980; Penalosa, 1980; Ramirez, 1985) point out the negative attitudes that some teachers have toward children who communicate in "non-standard English" format. These researchers further point out that these negative attitudes foster in turn a negative perception within the child of his or her own form of communication. Of course, some children are able to adapt quite well to a variety of communication styles. They are able to make transitions from one style of communication to another depending upon the setting. It is this group of children who seem to function the best and ultimately succeed within the school environment.

Impact of Culture on Family Systems

Understanding the role of family is key to understanding the child: This is true for children from any cultural group. Families impact growth, values, and identity development as well as academic achievement. Taylor (1989) found that among a college sample of African American youth, parents seemed to be the key element in identity formation. In contrast, Taylor's data from "inner-city low income" African American youth indicate a lack of identification with familial role models and a general mistrust of "others" as resources. This contrast between the two groups points out the role of other variables within the cultural frame, like socioeconomic status (SES). When looking at the Taylor sample it is hard to discern whether SES impacted the family interaction to such a degree as to circumvent its impact or if the "low income" group found familial structure from other sources and therefore rejected their own family.

Within various cultures however, the role of the family system, the modes of interaction with children, and the male–female relationships vary. The notion of correcting the behavior of children takes on different dimensions. Within the context of some Appalachian and African American families, physical punishment may be acceptable and understood or interpreted by the child differently. Therefore, it has a different psychological effect (Gray & Cosgrove, 1985). Physical punishment is often linked to theological notions of atonement for wrongdoing, to alleviate guilt for the "crime," clean the slate, and start anew. Gray and Cosgrove (1985) studied the child-rearing styles of six ethnic groups: Filipino, Japanese, Samoan, Vietnamese, Mexican-American, and Blackfoot Indian. There was great misconception about these varied styles of child rearing. The protectiveness of the Japanese and Filipino mothers and the physical discipline of the Samoans was believed by observers/raters to be harmful to the child, perceptions no doubt influenced by the specific cultural backgrounds of the observers/raters. The reader is referred to the study as a useful illustration of various ways families handle child rearing and the ways these practices are interpreted by others.

As various cultural groups are studied, a number of differences, as well as some similarities, emerge (Boykin, 1983; Hale-Benson, 1986; Hilliard, 1976). As stated in an earlier section of this chapter, stereotyping people by generalized characteristics is something that all must ward against. But the information from these sources when considered in relationship to the level of acculturation within the person/group (and not used as a blanket truth for all persons of that group) can facilitate an understanding of the complex maze of influences operating within a child's life. Culture is multileveled and influenced by numerous factors, but there are some shared dimensions within cultures and across cultures that are experienced by many people.

BEST PRACTICES: IMPACT OF CULTURE UPON PRACTICE

By considering and evaluating multiple environmental factors impacting a student, the school psychologist can better understand and work with that individual. There are several steps school psychologists can take and programs they can implement to better understand cultural factors and to enhance practice. First, school psychologists need to be informed about various perspectives on cultural differences and similarities. Reading critically the research suggesting quick solutions or one dimensional answers to complex cultural questions is important as is remaining flexible in thinking about the construct of culture. Careful selection of theories useful in practice is an important issue that should not be dismissed because of varied theoretical perspectives or differences of opinion nor because the cultural variability within groups often makes it difficult to conceptualize group characteristics. One key element in this whole notion of culture may be simply understanding the complexity of the issue and the multiple layers that impact it.

Second, school psychologists should examine critically their own ideologies about cultural diversity, revisit biased notions that may have been acquired during their upbringing, and tease out their own beliefs about culture that stem from training-program ideologies. Prejudices found within our society need to be carefully evaluated. In turn school psychologists can assist teachers and administrators in reframing their perspectives if needed. This can be done in a nonthreatening workshop or through in-service activities as well as in preservice clinical supervision experiences. Cultural diversity workshops that foster awareness, knowledge, and practice can also be beneficial.

Third, school psychologists could try to become familiar with the cultural experiences of the children with whom they work and the person-by-environment variables influencing the child's attitudes, beliefs, and behaviors. This requires a full examination of socioeconomic influence, gender, the family system, level of acculturation, traditions and customs, and the connections with ethnic communities or continents of origin of the families and children with whom they work. Suggestions for practice have recently been included in the "Guidelines for Providers to the Culturally Diverse" (American Psychological Association, 1993). To work effectively with diverse children, school psychologists could visit the various communities within their district, meet with families and/or leaders at community centers and churches, and treat the indigenous language (e.g., Spanish) with respect. School psychologists could gain insight into the numerous learner characteristics common to that culture. This process may also increase their chances of determining the degree to which instructional changes such as those offered by Hale-Benson (1986), Kunjufu (1984), and others is warranted (e.g., infusing culturally relevant tradition and material into the curriculum, changing teaching style).

Fourth, when prescribing interventions, school psychologists could use the family and community support systems inherent in the child's environment. These systems' agents could be involved in the assessment and intervention process and their recommendations should be requested and considered.

Fifth, school psychologists could identify how the systems of the larger society positively or adversely impact the child and should serve as advocates in ameliorating adverse conditions, whether this is the school, the family, or the criminal justice system. For example, if the classroom teacher is using a style inconsistent with the child's culturally influenced style, then the psychologist can help the teacher to change the way knowledge is presented to that child. On the other end of the spectrum, the system could be evaluated to determine its facilitative effect. These aspects of the child's experience should be fostered and expanded.

Sixth, school psychologists could become familiar with (a) assessment tools that address the multifaceted components of "intelligence" or "cognitive capability" and (b) various intervention issues. These are especially valid pursuits because research indicates that slightly more than half of the school psychologist's time is still used for assessment and a significant number of minority children are in special education or considered educationally at risk (Gopaul-McNicol, 1992b; Hutton, Dubes, & Muir, 1992; Reschly, Kicklighter, & McKee, 1988). For example, incorporating the Sternberg (1985) or Gardner (1983) view of multiple intelligence may be a more sensitive framework to use for conceptualizing the diverse capabilities present within individuals of nondominant cultural groups. Using assessment instruments normed with representative samples of cultural groups can also be helpful if those samples represent local numbers of ethnic and gender groups. This should not be the end point however; psychologists may need to go beyond this practice, to designing and using instruments conceptualized with cultural diversity in mind. It is possible that a more accurate assessment of learner capabilities may be produced by instruments that take into consideration possible brain-hemisphere-control differences. If cultural variations underlie the European-American analytical-left hemisphere and Native American holistic-right hemisphere epistemology, for example, assessment instruments should require students to demonstrate elements of both styles of knowing. Assessment tools that consider and accommodate culture/ethnicity to varying extents include

- Woodcock Johnson-R
- Escala de Inteligenica Wechsler para Ninos-R (WISC-1982)
- Kaufman Assessment Battery for Children (1983)
- Differential Ability Scale-5th Edition
- Test of Non-Verbal Intelligence-2
- Language Assessment Scales-Oral–Spanish and English
- Culture Free Self Esteem Inventory
- Vineland Adaptive Behavior Scales
- The "Who" and "U" Checklists (Hilliard, 1976)

Some of these tests are reported as being frequently used by school psychologists (e.g., Kaufman Assessment Battery for Children, Culture Fair Tests, Vineland, Test for Nonverbal Intelligence) (Hutton et al., 1992).

Because Native American learners have high creativity scores as measured by the Torrance Test of creativity, Tannehill (1992) suggests the use of creative instructional exercises for Native American children. Along these same lines, Florey (1986) outlines several issues to consider when working with Native American children and assessing them for "gifted" programs. For example, reliance on nonverbal communication, noncompetitiveness, and detailed verbal accounts can provide useful information. Mercer (1989) recommends the use of both an assessment tool and a curriculum that tap into the optimal ability of culturally diverse children. The notion behind this approach is the belief that optimal performance is developed and can be attained by all through practice. When using the Optimal Performer Locator, the child is introduced to materials culturally relevant to him or her. The tasks tap into all modes of functioning (e.g., tactile, kinesthetic, cognitive) and if the child's performance initially fails to match desired outcomes, behaviors are modeled and children are reevaluated to determine if skills have been acquired. The goal is to measure the highest level of functioning for that child. This same perspective is supported by the System of Multicultural Pluralistic Assessment (SOMPA; Matthew, 1992). The assumptions of this model are that (a) many normal curves for behavior are necessary for assessment, (b) one cannot compare people of different cultures, (c) multiple measures should be used, and (d) a multicultural perspective should be a part of the assessment philosophy.

Seventh, school psychologists could use qualitative as well as quantitative assessment tools with diverse groups of learners. These might include anecdotal records, observation, post facto work, and interviews. Again, using indigenous consultants during the assessment and intervention process is important during this phase.

Eighth, school psychologists should become acquainted with the use of a multidisciplinary team approach, such as the PACTS model (Savage & Adair, 1980) where children are examined from a cognitive, social, emotional, cultural, and behavioral perspective with an array of techniques including observation, interviews, and paper-pencil instruments. This provides a more holistic view of events and characteristics surrounding the child in question.

Programmatic Examples

Numerous programs have been developed to address the dilemma of facilitating rather than negating the diverse cultural influences on youth and their consequent behaviors. Most of these programs exist outside of the regular curriculum; however, psychologists working within school settings can be mindful of these successful programs and work toward cultural inclusion. A few programs are highlighted here:

Winners: The Key to Success is Effort (Murray & Fairchild, 1989). This 10-week program consists of workshops geared toward supporting the academic success of African American junior and senior high students. The program uses attribution therapy (Diener & Dweck, 1978), expectancy training, internal speech as a self-monitoring device (Meichenbaum & Goodman, 1971), and social modeling techniques (Sarason & Ganzer, 1973).

The 16 outcomes connected with this program range from identifying and understanding the causes of school difficulties to increasing self-confidence and image to establishing values and goals.

Cultural Enrichment Programs such as Simba Wachanza Program (Swahili for young lions), W.E.B. DuBois Program, and many other programs modeled after the suggestions of Kunjufu (1984). They advocate the use of African traditions, educating about African and African American culture, and validating the participants' sense of self. These programs (a) have a culturally sensitive mission, (b) emphasize leadership, (c) have high expectations, (d) frequently monitor student progress, (e) possess a positive learning environment, (f) provide sufficient opportunity for learning, and (g) support parent/community involvement.

Some schools (Marva Collins, African American boys schools, schools for girls, etc.) adhere to this framework. In communities where these schools are not available, after-school programs can be and have been created with this cultural slant in mind.

Kamehameha Early Education Project (KEEP). This program was developed to assist Hawaiian children with reading acquisition skills. It is infused with cultural-specific patterns of behavior and language characteristics (Foster, 1992).

Reading and Language Skills. A collaborative project sponsored by the University of Arizona and the Bureau of Applied Research in Anthropology and geared for Mexican American children focuses on reading and language skills (Foster, 1992).

SUMMARY

The role of the school psychologist in the lives of children is often crucial for their long-term school success. School psychologists should not forget the importance of knowing all children and the *whole* child. The challenges of understanding children from various cultural frames and helping to meet their needs may seem overwhelming at times. It may help, when considering cultural factors within the school system, to remember three basic words: balance, awareness, and context. As illustrated by the numerous authors cited here and elsewhere, culture may be viewed from several perspectives (Frisby, 1992). Psychologists may need to transform their own and others' thinking about culture from a fragmented and yet sometimes one dimensional view to a more diunital and integrated one. A balanced view that includes multiple aspects of the child's life increases the chances of generating appropriate assessments and interventions. In addition, being constantly aware of multiple cultures and the impact of these cultures may assist the school psychologist in providing effective consultation to teachers, families, and community agencies. And, the infusion of cultural sensitivity facilitates the development of *all* people as we strive to interface with a world that is truly diverse.

Finally, Lewin's (1935) notion of environmental context can provide a frame with which to examine the "cultural" picture. Examining multiple aspects of the person as well as the environment or context from which he or she came (as well as their present context) brings to light the complexity and importance of culture. In the practice of school psychology, it is critical to understand the multiple layers and interconnectedness of cultural influences: They cannot be ignored nor oversimplified. Attention must be paid to such environmental factors as

1. Messages passed on from generation to generation, coupled with the present day atmosphere in which those messages are received.
2. The pervasiveness of those messages.
3. The nature of those messages.
4. The ways they are connected to the culture of origin.
5. Conflicting messages from other sources.
6. The power of the other sources.
7. The child's own view and level of understanding.
8. The degree to which these messages are compared to, confirmed by, or discounted by the person's own experiences.

Weighing the various elements within the environment facilitates a deeper understanding not only of the child but of the connections between one's own experiences and those of the child (a good basis for developing relationships) and of the differences and similarities that may exist.

A few final issues to keep in mind are

1. Remain aware of the systemic impact upon the child (macrosystems to mesosystems to microsystems).

2. Evaluate the cultural milieu of the child and the degree of acculturation.

3. Evaluate strengths of the culture of origin and its adaptive characteristics.

4. Focus on development/readiness and all aspects of cognitive style.

5. Become aware of characteristics influenced by culture that may have an impact on assessment and intervention results.

6. Become aware of one's own view of culturally diverse populations and remain flexible in one's interactions with children from these populations.

7. Actively seek the input of family members of the child with whom one is working and work collaboratively as advocates for the child.

Best Practices in Promoting Alternatives to Ability Grouping

Margaret M. Dawson
Center for Learning and Attention Disorders

OVERVIEW

"To ensure educational equity and excellence for all America's youth, NASP supports the creation of inclusive classrooms that are based on the belief that *all* students can learn — a core value of all schools in a democracy. NASP believes that tracking, or whole class ability grouping, is not consistent with that core value" (NASP, 1993). Thus begins the Position Statement on Ability Grouping passed by the Delegate Assembly of the National Association of School Psychologists in April 1993. In so doing, NASP joined numerous other national associations, consortia, and task forces in issuing a call for alternatives to ability grouping. Among the groups that have called for an end to tracking are the following: the National Education Association, National Association of State Boards of Education, National Association of Elementary School Principals, National Advocates for Children, Committee on Policy for Racial Justice, Education Commission of the States, National Middle Schools Association, National Commission on Secondary Schooling for Hispanics, and the Children's Defense Fund.

Despite these widespread calls for change, ability grouping remains firmly entrenched in many schools throughout the United States. This failure on the part of local school districts to act to promote what has been called the single change that would produce higher student achievement in our schools (Paul, 1992) may be due to two reasons: (a) Members of the school and community at large fail to see the need to promote alternatives to ability grouping; and (b) they may see it as important but lack a blueprint to implement alternatives.

This chapter will provide the tools necessary for school psychologists to play an activist role in promoting alternatives to ability grouping within the school districts in which they are employed. To accomplish this, three major areas will be addressed: (a) a brief review of the research on ability grouping which establishes the negative effects of this practice; (b) an overview of a process that can be used to implement alternatives to ability grouping; and (c) descriptions of specific alternatives to ability grouping that have been implemented in schools throughout the country.

BASIC CONSIDERATIONS

Summary of Ability Grouping Research

Statistical evidence. Ability grouping has been the object of extensive research since the beginning of this century, with comprehensive reviews of the research appearing several times each decade since the 1920s. While early reviews were of a narrative nature, in recent years researchers have employed more objective meta-analyses as a means of synthesizing the findings and drawing conclusions about the effects of ability grouping. These reviews by Slavin (1986, 1990) and Kulik (e.g., Kulik, 1992; Kulik & Kulik, 1982) have generally reached similar conclusions, although the authors interpret the findings somewhat differently.

Slavin (1986) reviewed the effects of five grouping plans on achievement at the elementary level: ability-grouped class assignment, regrouping within grade levels for math and/or reading, cross-graded grouping, comprehensive nongraded plans (using a continuous progress program), and within-class ability grouping. Slavin concludes that there is no evidence to support ability-grouped class assignment, and the research on within-grade regrouping is inconclusive. Slavin's analysis finds support both for cross-graded grouping and for comprehensive nongraded programs. The use of within-class ability grouping is supported for math. No studies have been conducted on the use of within-class ability grouping for reading, despite the fact that this is likely the most widespread use of ability grouping at the elementary level.

At the secondary level, Slavin (1990) looked at studies comparing ability-grouped classes with heterogeneously grouped classes. Meta-analyses looking at a total of 29 studies, as well as various subgroups of those studies, yielded effect sizes of nearly zero in all comparisons. Thus, ability grouping at the secondary level does not have a positive effect on achievement. Slavin points out that very few of those studies were completed above the ninth grade, although he concludes that "the more limited evidence that does exist from studies in Grades 10–12 also fails to support any effect of ability grouping" (Slavin, 1990, p. 494).

Slavin draws several other conclusions from this review. First, there are no differences in outcomes whether students are assigned to classes based on one composite ability or achievement measure or are assigned to classes based on specific subject performance measures. Second, ability grouping appears to be equally ineffective in all subject areas, although there is some evidence that it is more detrimental in social studies. Finally, there are no consistent positive or negative effects of ability grouping on students of high, average, or low ability.

Kulik (1992) also conducted meta-analyses on ability grouping research, although he expanded his study to include programs for gifted and talented students. While he and Slavin reach similar conclusions on the studies they looked at in common, Kulik found support both for accelerated programming (either by compressing instruction or having students skip grades) and for enrichment programs. Slavin (1991) has pointed out that there are serious methodological problems with most of the studies of enrichment programs, and makes an added point that makes the research in this area questionable: "Even if enrichment programs were ultimately found to be effective for gifted students, this would still leave open the possibility that they would be just as effective for *all* students" (p. 69).

Sociological evidence. The research cited thus far are all experimental studies looking at controlled comparisons of students placed in homogeneously and heterogeneously grouped classes. These studies might lead one to conclude that while ability grouping does not appear to be particularly helpful, neither does it appear to be harmful to students of any ability level. Another body of research exists, however, that challenges that conclusion. Sociological studies have investigated the differences between high- and low-ability classrooms on a wide range of factors that are considered to be strongly associated with school achievement. These include teachers' expectations, classroom climate, peer group norms, curriculum content, and instructional practices. Reviews of this research led educational psychologist Lorrie Shepard to conclude recently, "These studies consistently show alarming differences in educational quality between high- and low-track classrooms" (Shepard, 1992). And Gamoran and Berends (1987) concluded from their review of over 50 ethnographic studies on the effects of stratification in secondary schools that "the balance of the evidence suggests to us that grouping and tracking do affect achievement, despite the inconsistencies in survey analyses" (p. 431).

A summary covering the scope of this research was completed by Dawson (1987). Examples from elementary and secondary research are provided by way of illustration here.

Reading research affords good examples that detail differences in instruction available to high and low achievers at the elementary level. While research studies comparing grouped versus ungrouped reading instruction are available, numerous studies (e.g., Eder, 1981; Gambrell, Wilson, & Gantt, 1981; Rist, 1970) have shown that students in low-reading groups receive poorer quality instruction, evidence less time on task, and spend less time engaged in those activities most strongly correlated with high reading achievement than students in high-reading groups. It is likely that these effects take their toll: Weinstein (1976), for instance, found that when initial reading ability was controlled for, the reading performance of students in low-reading groups declined significantly compared with the performance of students in high-reading groups over the course of first grade.

At the junior high school level, one large-scale study (Evertson, 1982) found that teachers in high-ability classrooms were more clear in their instructional presentation, more consistent in dealing with behavior, and were better able to maintain task orientation. Teachers in low-ability classrooms tended to spend more time on classroom management and were more likely to reinforce off-task behaviors of students. And at the high school level Oakes (1985) also found greater clarity of presentation, teacher enthusiasm, task orientation, and avoidance of strong criticism in high-track classes than in low-track classes. Other advantages that high-track students have include being assigned teachers who are more experienced and more skilled and having access to more of the knowledge that is required for college entrance exams (Gamoran & Berends, 1987). With respect to students' behavior, higher-ability classes and higher-ability students have been found to exhibit better work habits, motivation, persistence, and self-confidence, as well as greater participation (Veldman & Sanford, 1984), thus contributing to a classroom atmosphere that is more conducive to learning. By way of contrast, for a compelling picture of life in lower-track classrooms, see Page's (1991) extensive ethnographic study.

Recent years, however, have seen many schools and districts begin to tackle this difficult issue. Out of their experiences have come important lessons on how to achieve school- or district-wide change. The next section will discuss processes that have been found to be effective in helping schools adopt alternatives to ability grouping.

BEST PRACTICES

Educators involved in helping schools "untrack" have learned two important lessons: (a) Untracking is most successful when it is carefully planned — where input is sought from a variety of constituencies and where a process of gradual change is designed with full participation of those affected by the change; and (b) successful untracking requires changing the way classrooms are structured and the way learning takes place.

A Process for Change

Untracking can be implemented by individual teachers and schools and on a districtwide level. Within a classroom, teachers can explore alternatives to traditional reading group instruction by using a mix of homogeneous and heterogeneous grouping, placing children in groups based on interests rather than ability, encouraging students to visit other reading groups, and reassessing and reassigning students frequently. Cooperative learning is an effective way to untrack in math or other content area subjects. Individualized instructional approaches such as the writing process (Grave, 1983) and building in daily silent reading time also facilitate untracking.

When individual schools untrack, it is usually because the principal has a strong commitment to heterogeneous grouping. Slow and careful planning characterizes the most successful of these efforts. One elementary school principal reported that the process she followed included disseminating research and articles on ability grouping, putting together study groups to discuss the research, sending teachers in small teams to visit other schools in the area that used mixed-ability groups, and introducing the change gradually, starting in only *some* classes at the lower grade levels before expanding out to include all classes, first at the lower, then at the higher, grade levels.

The process is more difficult but the effect more profound when untracking takes place at a district level. For this to be successful, some key ingredients appear to be essential to make the process go smoothly. A brief outline of steps to follow to implement district-wide untracking, adapted from George (1992) is as follows.

Appoint a steering committee to study instructional grouping. Key individuals should be identified to head the steering committee — people who, based on their status within the community as leaders and opinion makers, can lend authority to the process just by nature of their participation. The steering committee itself should represent the key constituencies affected by the change process: school board members and administrators, teachers, parents, and other community leaders. Consideration should be given to including student representatives from both high- and low-track classes. George (1992) points out that two sets of parents, in particular, should be part of the process: those who believe their students benefit from tracking and those who feel their children are hurt by it. With the first group, the task is to reassure parents that their children's educational prospects will not be harmed by a move to heterogeneous grouping, while the second group of parents need to be encouraged to "speak out against what they believe to be unjust and unfair practices and be encouraged to insist on equity in the assignment of students, teachers, and school resources" (p. 27).

The task of the steering committee is to review research findings and legal decisions and, in combination with information about local grouping practices, to make recommendations to the school board for new grouping practices.

Establish local self-study to assess the impact of grouping practices within the local school community. Change is more effectively implemented if results of national research can be supplemented by local-level research that investigates conditions specific to the school district that is planning for change. Questions that such a self-study might address include the following (taken from George, 1992): (a) How are students assigned to classes? (b) Is there proportional representation in all ability groupings of all ethnic and social-class groups? (c) How flexible are the grouping arrangements — do students assigned to particular groups tend to stay there over the length of their school careers? (d) How does ability grouping affect students' perception of themselves, including measures of self-esteem and future aspirations? (e) Does track placement affect students' behavior, as measured by discipline referrals, detentions and suspensions, their participation in extracurricular activities, their rates of absenteeism, and so forth? (f) How are teachers assigned to different tracks — do all teachers share equally in teaching both high- and low-track groups? (g) Are there differences in how high- and low-track classes are taught — are lessons prepared differently, are different instructional strategies used, are there different expectations, and so on? (h) Is parent involvement in school programs equally distributed across ability groups? Looking at these issues can bring to light significant disparities between high and low tracks across a broad set of dimensions that can make a compelling case to support untracking.

Disseminate findings to a wide audience. The results of both published research and self-study need to be made available to as wide an audience as possible. George (1992) notes that well-educated parents can become valuable allies in promoting change when confronted with research that both demonstrates the inequities associated with grouping and assures them that their children will not be hurt by untracking.

Wheelock (1992) describes a workshop activity for parents that powerfully illustrates the inequities of ability grouping. Developed by the Right Question Project, in Somerville, Massachusetts, workshop participants are given two sheets of paper stapled together. On the first sheet is written "What Your Child Should learn: The Curriculum for All the District's Schoolchildren." The second page contains the sentence, "The full curriculum is 100 pages long." On half the papers, a second sentence reads, "Your child will be taught the full 100-pages," while on the other half a second sentence reads, "Your child will be taught only the first 50 pages." The project director reported that this exercise leads parents to ask important questions such as "Why is my child only being taught 50 pages?" "Who made that decision?" "Why was it made?" "Am I supposed to be involved? Can I be?" (Wheelock, 1992, p. 83). Raising and discussing these questions leads parents to new insights into how grouping decisions are made and the consequences of those decisions.

Develop a board-approved policy statement on grouping for instruction. Such a statement should be developed by using all the information collected by the steering committee, including results from national research and local self-study and with input from a broad spectrum of the school community. Such a statement becomes a values statement that then drives the development of a long-range strategic plan.

Design a long-range strategic plan. Such a strategic plan will likely be a multiyear plan and should identify broad goals for reorganization as well as define specific objectives and identify the strategies required to ensure success. A phase-in-process either may target certain aspects of grouping practices to be addressed first or may determine that regrouping shall occur at younger grade levels or in some schools before others. A process for monitoring progress, for trouble-shooting and problem solving, and for evaluating the outcomes of untracking should be incorporated into the plan.

Implement extensive staff development to help staff prepare for untracking. To be effective, staff development cannot be a one-shot overview. It must be ongoing, with components in place before, during, and after full implementation of untracking. George (1992) outlines a number of components to staff development that appear to be critical to the success of the process. Teachers must have (a) access to national and local research on the effects of ability grouping, (b) the opportunity to discuss moral and philosophical issues inherent in ability grouping, and (c) extensive training in instructional strategies and alternative grouping arrangements that ensure that less-able students are sufficiently supported while more-able students are sufficiently challenged in their learning efforts.

Change is never easy. Advocates for untracking may become impatient when confronted with the need for a multiyear plan in the face of the day-to-day inequities they see in schools that distribute resources unequally to students of different ability levels. Experience has taught, however, that hasty change too often leads to failure, and the ensuing bad feelings act as a serious impediment to future reform attempts.

ALTERNATIVES TO ABILITY GROUPING

Goodlad, in his massive study of schooling reported in *A Place Called School* (1984) described schools as consisting predominantly of classrooms where teachers explain and lecture and where students listen to teachers, write answers to questions, and take tests and quizzes. For untracking to be successful, schools must find methods that more effectively engage students and make learning real, interactive, and relevant for future life outcomes. For heterogeneous grouping to be successful, diversity will not only need to be acknowledged, it will need to be embraced. As adults, we draw on the strengths, aptitudes, and interests of those around us to increase productivity on the job and harmony in the home. Surely, if we create classrooms that allow students to do the same, we will create a better match between what happens in schools and what happens in the world beyond the schoolhouse door.

Effective instruction in heterogeneous learning groups may best prepare today's students for life after high school, but it cannot be accomplished by continuing to use traditional teaching and learning models. Brief descriptions of alternative grouping patterns, instructional strategies, and curricula that support learning in mixed ability groups are presented below.

Alternative Grouping Arrangements

Partial untracking. If it is politically inexpedient to curtail tracking altogether, a first step in the process may be to reduce the number of tracks, eliminate the lowest tracks, or make it easier for students to enroll themselves in higher tracks. Many school districts encounter the strongest resistance from parents when attempts are made to eliminate honors courses; hence it may be unwise to do this in the early stages of untracking. At the same time, efforts can be made to ensure that enrollment criteria for honors courses are fair and that all ethnic and social-class groups have equal access to these courses.

Flexible grouping/team teaching. This is the practice of using different grouping arrangements for different purposes. It may mean a schedule of homogeneous grouping two times a week and mixed-ability grouping three times a week, for instance. Or it may mean clustering students differently for different teaching units (e.g., homogeneous grouping for a study skills component of a social studies class). Sometimes, flexible grouping is combined with team teaching — by combining large, whole-group activities with smaller-group activities, with more teachers available to work with smaller groups. The social studies department of a small junior high/high school in northern Vermont, for instance, arranged teaching schedules so that all seventh-grade social studies classes were taught simultaneously. This gave teachers great flexibility in how they taught the curriculum and grouped the students.

Mixed-ability grouping with additional support. Placing all students in mixed-ability classes but offering extra support to students who need it is one grouping strategy that recognizes that students have different needs and learn at different rates. When Parkway North High School, outside St. Louis, Missouri, untracked several years ago, teachers added English Skills and Skills Tutorial Programs to provide students the skills they needed to survive in the mixed-ability classes (Merina, 1990). The added class periods enabled teachers to fill in gaps, do preteaching to enable students to better participate in class discussions, and establish closer relationships with students. Other models provide before- or after-school assistance to students who need additional help. Some schools hire college students to provide tutorial services; peer tutoring is an additional way to provide supplemental help to students who need it.

Instructional teams. At the middle school or junior high level, heterogeneous grouping appears to be most successful when students are divided into clusters within a school, with a team of teachers assigned to each cluster. Often, specialists, special educators, and instructional aides join the teams to provide additional support. Each team has a common planning period that enables them to discuss students or management problems and to develop interdisciplinary or thematic units where appropriate. While teams can make heterogeneous grouping successful, when employed in ability-grouped schools such teams have led to untracking as teams of teachers begin to question the quality of instruction they are providing to low-track students (Wheelock, 1992).

Cross-graded grouping. Also known as the Joplin Plan, this approach has research support when it is done with one or two subject areas such as math or reading (Slavin, 1986). It is a form of heterogeneous grouping, since younger high achievers may be placed with older low or average achievers. However, it allows teachers to work with a narrower range of skill levels, enabling them to use more whole-class, teacher-directed instruction.

Nongraded schools Nongraded schools do not assign students to grades; rather, teams of teachers are assigned to groups of students who are heterogeneously mixed by age and ability and are frequently regrouped depending on the nature of the learning task. Progress is determined by tasks completed or skills learned. Learning activities consist predominantly of complex problem-solving tasks that are of an interdisciplinary nature. Students are active participants in their own learning process. A recent review of 57 studies (Pavan, 1992) found that in 91% of those studies, students in nongraded schools performed as well as or better than students in traditional, graded schools. Students in nongraded schools also performed higher on measures of self-esteem and attitudes toward school. Longitudinal studies show the positive effects of nongraded schools hold up over time. Additionally, at-risk students performed better in nongraded schools.

Alternative Instructional Strategies

Cooperative learning. Cooperative learning is an instructional strategy in which learning takes place in small, heterogeneous groups carefully selected to represent a diversity of learning abilities. As most commonly practiced, students are responsible for helping each other master material or complete learning activities, incorporating individual accountability (ultimately, each student must demonstrate that he/she has learned the material) and group rewards for performance. Often, the rewards, which may be as simple as a certificate of achievement, are based on *improvement* on previous week's performance. This allows students of all abilities to contribute equally to the group's accomplishments. Cooperative learning has been shown to improve achievement, enhance attitudes toward school and self-concept, and facilitate cross-ethnic friendships and the mainstreaming of handicapped students (Slavin, 1983). This approach, which is now widely used throughout the United States, perhaps holds the best promise for reducing reliance on ability grouping.

Peer tutoring/cross-age tutoring. The use of student tutors allows for more active learning, more opportunities for individual response, and more immediate feedback. Meta-analytic research (Cohen, Kulik, & Kulik, 1982) has demonstrated that peer tutoring has positive effects on academic performance and attitudes of both tutors and the tutored. This approach is one way to provide additional support to students who need it in mixed-ability classes.

Seminar discussions. Long the instructional method of choice in this country's exclusive college preparatory schools, the use of seminars to help students grapple with complex information and questions for which there may be no right answer is also applicable to mixed-ability classrooms. Used primarily for discussions involving text interpretation, it is most successful when teachers begin discussions by posing open-ended interpretive questions for which text material can be found to support several alternative answers. Students become enthusiastic participants when they see that the teacher is genuinely open to a variety of answers and is not pushing students toward predetermined responses.

A discussion format such as this can produce results that are surprising to teachers. Cushman (1992), in writing about seminars with mixed-ability groups, stated, "Higher-performing students who are more comfortable with written texts learn to accept that sometimes there is no one answer with which they can please the authorities as they are used to doing. Less skilled students learn that their candor and rich life experience are assets in an academic discussion" (p. 1). A teacher who taught a mixed-ability English class for the first time reported, "The honors and college bound students were simply repeating material they already knew, parroting back what I had said. The general track students questioned them, forcing these 'academics' to clarify what they meant and put their ideas in terms everyone could understand" (Steinberg & Wheelock, 1992).

Hands-on/experiential learning. Activity-oriented learning lends itself to heterogeneous classrooms, and a number of specific curricula have been developed explicitly for use in mixed-ability classes. Such approaches combine learning by doing with teaching higher-order and creative-thinking skills. As an example, one of the junior-high-level projects developed by FAST (Foundational Approaches in Science Teaching) requires students to create a model submarine that can "rest on top of the water in a fish tank for five seconds, submerge, remain on the bottom of the tank for one minute, rise to the surface, and repeat the cycle" (Wheelock, 1992, p. 174). See Wheelock (1992) or Steinberg and Wheelock (1992) for descriptions of additional resources.

Project-oriented learning. Having students create a class store or newspaper, put together audio interviews of community workers, or produce a video tape depicting a community's history are all examples of project-oriented learning. These approaches often tap important communication skills that allow learners who are weak in traditional academic skills to display their talents.

Individualized instruction. This does not have to mean that a teacher creates 25 separate lesson plans for each student in the classroom. It *does* mean building in opportunities for differentiated instruction depending on the needs and interests of students. The following are examples of ways to individualize instruction.

1. Defining desired learning outcomes and giving students choices about how they will demonstrate that they've achieved those outcomes. When teachers begin by defining broad learning goals that they expect students to accomplish, this allows for significant flexibility in how students will accomplish these goals and how they will demonstrate mastery.

2. Having students design their own homework assignments.

3. Preparing activities at different difficulty levels that students can choose from to reinforce or extend their skills. A learning-center approach to instruction lends itself to this.

4. Negotiating learning contracts with students to enable them to earn specific grades by completing specific tasks or demonstrating specific competencies. One teacher in a high school in New Hampshire lists a vast array of activities and responsibilities (both in class and out of class) with points attached to each item. Course grades are determined by how many points students accumulate.

5. Allowing students to retake tests until they demonstrate mastery. Tests can be individualized in other ways by adapting the format and content to meet the needs of individual students. Portfolio assessments lend themselves to the assessment of *progress*, perhaps the most relevant form of student assessment.

Curricular Modifications

A recent national study, conducted jointly by the American Society for Training and Development and the U.S. Department of Labor, that details the kinds of skills employers seek in employees offers a compelling reason why school reform must include a more relevant curriculum for life in the *twenty-first century. Published in a book entitled Workplace Basics: The Skills Employers Want* (Carnevale, Gainer, & Meltzer, 1991), the study is based on interviews with hundreds of employers from a wide array of companies and organizations. The study includes a list of skills that employers seek in new employees. As summarized in *Education Week* (Marshak, 1993), the desired skills fall into seven areas: reading, writing, and computation skills; listening and speaking skills; "learning to learn" skills; problem-solving and creative-thinking skills; personal-management skills; teamwork skills; and leadership skills and organizational effectiveness.

Traditionally, schools have been most explicit in defining the reading, writing, and computation skills expected to graduates. This study suggests that greater emphasis needs to be placed on developing creative-thinking and problem-solving skills and the skills required to work well with other people. These skills are best taught and nurtured in an environment that is defined by diversity, not homogeneity.

Many of the instructional strategies described above address these skills. Through cooperative learning, seminar discussions, project-oriented learning, and hands-on, experiential learning, students learn to think through problems, devise creative solutions, listen to alternative viewpoints, and tap into the skills of others to achieve common goals. Thus, many of the skills described above can be infused into an existing curriculum by altering the way that curriculum is taught. Examples of specific curricula that have been developed to facilitate students' acquisition of higher-order thinking and problem-solving skills, as well as the skills required to work well with people, are briefly described below:

The HOTS Project. As described by Wheelock (1992), the HOTS (Higher Order Thinking Skills) "is a general thinking program designed to help students deal with several concepts simultaneously, engage in dialogue about ideas, think in terms of general principles, and pursue ideas to their logical conclusions" (p. 163). This program uses computer games such as "Oregon Trail" or "Where in the World is Carmen San Diego" as a jumping-off point, with teachers posing questions about how students make choices and reach conclusions. Although it was designed originally as a pull-out program for at-risk students, many schools use it effectively in heterogeneous learning groups. For more information, contact HOTS Project, College of Education, Division of Educational Foundations and Administration, University of Arizona, Tucson, AZ 85721.

Philosophy for children. This is a 12-grade curriculum designed to teach critical-thinking skills through the discussion of philosophical issues raised in stories that can be incorporated into a language arts, reading, or study skills curriculum. Evaluation studies have documented gains in reading and reasoning skills in students of all ability levels (Wheelock, 1992). For more information, contact the Institute for the Advancement of Philosophy for Children, Montclair State College, Upper Montclair, NJ 07043.

Junior Great Books Curriculum. This is a thinking skills curriculum that uses good literature to enable children to explore open-ended, interpretive questions. Selections are limited in length to permit reading and rereading; they lend themselves to extended interpretation through ambiguity of meaning, and they raise puzzling questions for both teachers and students. In addition to improving thinking skills, school districts employing this curriculum report substantial improvements on measures of reading vocabulary and comprehension. One elementary school in Pennsylvania reported that after 1 year, 50% of students considered "remedial" tested out of that classification (Wheelock, 1992). This approach appears to be particularly successful in heterogeneous classes. Wheelock (1992) quotes a middle school teacher about its use in this kind of classroom: "In homogeneous groups, the discussions used to drag; there wasn't a spark. But in the discussions in heterogeneous classes, the best thing about them is the mix of perspectives. . . . The kids ask questions because they're really curious, not just for the grade" (p. 162).

Practical-Intelligence-for-School (PIFS). Practical intelligence refers to the ability to understand and apply "tacit" knowledge to learning situations. Tacit knowledge is "knowledge that is not explicitly taught or even verbalized, but is necessary for an individual to thrive in an environment" (Sternberg, Okagaki, & Jackson, 1990). Together with Howard Gardner at Harvard University, Robert Sternberg has developed a curriculum to teach students the tacit knowledge they need to succeed in school. Three kinds of tacit knowledge are covered in this one-semester course, which includes a student text and a comprehensive teacher's manual, along with curricular material on managing oneself, managing tasks, and working with others. Students learn the self-management skills that are necessary to take in new information, demonstrate learning, and use new skills. They learn how to get organized, seek help for problems, manage time, and apply study skills. They are also taught communication skills and how to make good choices in school. For more information, contact Robert Sternberg, Yale University, Department of Psychology, P.O. Box 11A, Yale Station, New Haven, CT 06520-7447.

Cognitive strategy instruction. A number of cognitive strategy curricula have been developed to help teachers teach students procedures for accomplishing academic tasks. Coming from the field of cognitive psychology, extensive research has been done over the years on cognitive and metacognitive strategies that can enhance performance in a variety of academic areas, including reading decoding, reading comprehension, spelling, written language, and math problem solving. Since these strategies teach students to become more active and self-directed in their learning, they suggest application to heterogeneously grouped classrooms. Examples of cognitive strategy curricula are those developed by Deshler and his colleagues (Deshler & Schumaker, 1988) and the Benchmark School (Gaskins & Elliot, 1991). See also Pressley et al. (1990) for a comprehensive research-based review of cognitive strategies.

Role of the School Psychologist in Promoting Alternatives to Ability Grouping

Many school psychologists do not see it as their role to become involved in influencing policy or promoting school reform. And yet school psychologists are often in a good position to do just that, either through informal sharing of information with teachers and school administrators or through more formal participation on task forces or strategic planning committees. Because school psychologists are in contact with students who are not succeeding in school, they are often in the best position to see how the way schools are structured contributes to learning failures. Ability grouping is one such structure that does not serve students well.

BEST COPY AVAILABLE

Students from lower-track classrooms are often referred to school psychologists for learning or behavior problems. In designing effective interventions or in making decisions about the need for special education, it is important for school psychologists to be aware of the effects of lower-track classrooms on students' behavior, effort, and motivation on teachers' and students' morale, and on classroom climate. When asked to facilitate the mainstreaming of students with disabilities into regular classrooms, school psychologists need to be aware that ability grouping makes mainstreaming decisions difficult, because the disparity between skill level and ability in many youngsters with disabilities makes assignment to appropriate classrooms difficult.

And school psychologists who engage in systems consultation need to be aware of the effect of grouping practices on discipline referrals, participation in school and extracurricular activities, and long-term career goals and aspirations. To look at individual students' problems, or even schoolwide problems such as discipline referrals, and fail to consider how grouping practices affect them may limit the options that schools have to address these problems. School psychologists, with their unique systems perspective, may be in an ideal position to help schools move toward untracking.

What are some actions school psychologists can take to promote alternatives to ability grouping? Here are a few suggestions.

1. Share with administrators the research on ability grouping and the NASP Position Statement on Ability Grouping (see Appendix A), as well as information about how schools can go about implementing alternatives to ability grouping.

2. Organize or participate in study groups to investigate grouping practices and discuss alternatives. There are usually some teachers in every school who are open to the idea of untracking. Bringing a group together to discuss issues and think about change can be a first step in bringing about significant changes in grouping practices.

3. Volunteer to serve on schoolwide or districtwide committees dealing with policy issues. Even if the focus of the committee is not on grouping practices, questions can be raised about how tracking or ability grouping may affect the issues under consideration. For instance, a task force assembled to study standardized achievement testing could prompt questions about the performance of different curriculum tracks and their rate of progress over time.

4. Conduct a self-study of grouping practices within the school district and share the findings with school administrators. Look particularly at issues of disproportionate representation of minority or lower-socioeconomic-status group membership in lower tracks, since concern about discrimination may prompt administrators and board members to take action where other findings may not.

5. Proceed with caution. There are certain "hot topics" in education that engender strong feelings and create tensions and conflict among diverse members of the school community. Ability grouping is one such topic. School psychologists will likely be most effective in facilitating change by taking a low-key approach — by sitting down with an administrator in a relaxed and collegial atmosphere, for instance, to have an open discussion about grouping practices and whether consideration has been given to pursuing alternatives, by sharing a few pieces of written material, such as brief summaries of the research, and arranging a follow-up meeting to discuss the administrator's reactions; or by gaining an administrator's support for assembling a study group to investigate the issue. If these approaches are not successful, school psychologists will need to make a personal decision to take a more activist stance. In our efforts to promote optimal learning conditions for all learners, school psychologists are sometimes forced to make difficult decisions regarding when to speak up and what tactics and strategies to employ for maximum effectiveness.

SUMMARY

Ability grouping has been widely practiced and extensively researched in the United States throughout this century. While controlled experimental studies have failed to find significant differences in achievement between students placed in homogeneously grouped classrooms and those in mixed-ability classrooms, sociological and ethnographic studies have consistently found substantial differences between higher- and lower-track classrooms. The conditions that are associated with high achievement are far more prevalent in higher-track classrooms, while lower-track classrooms are characterized by emphasis on classroom management, more off-task behavior, low student and teacher morale, and a classroom climate that is not conducive to learning. Furthermore, mixed-ability classrooms have been shown to more closely resemble average- or high-track classrooms on a variety of dimensions.

Schools and districts that have successfully moved away from ability grouping have planned for change carefully and have implemented change slowly, usually following a multiyear strategic plan. Involvement of key constituencies, including parents, teachers, and administrators, has been secured, and extensive staff development in alternatives to ability grouping is an integral part of the process.

Schools that successfully group children heterogeneously do not simply apply traditional teaching structures to mixed-ability groups. Rather, these schools recognize that regrouping for diversity requires changes in organizational structures, instruc-

tional models, and curricula in order to ensure that all students are both challenged and supported in an environment that promotes optimal learning for all. There are a wide variety of ways that schools can achieve this, and each untracked school is unique in the choices it has made. What these schools have in common is a sense of purpose and excitement and a realization that diversity is not an obstacle to learning, but a tool. School psychologists have an important role to play in sharing the research on ability grouping and its alternatives, participating in discussions to promote understanding of this research, and planning for a successful transition from tracked to untracked schools.

ANNOTATED BIBLIOGRAPHY

Dawson M. M. (1987). Beyond ability grouping: A review of the effectiveness of ability grouping and its alternatives. *School Psychology Review, 16,* 348–369.
This review article offers a concise overview of the research on ability grouping, including effects on achievement, self-concept, and attitudes toward schools. Sociological research is also reviewed that documents grouping effects on classroom climate, teacher expectations, instructional practices, and student behaviors. Alternatives to ability grouping are also discussed, including suggestions for effective grouping patterns, reading instruction for low-reading groups, and communicating achievement expectations.

Murphy, J. (1988). Equity as student opportunity to learn. *Theory Into Practice, 27,* 145–151.
This article discusses ability grouping as an equity issue. Research is cited to demonstrate that students in lower-track classes are discriminated against by depriving them of the same quality of instruction, restricting access to the same kinds of knowledge, and exposing them to less instructional time than is available to higher-track students. A useful table summarizes these differences between high- and low-track classes.

Paul, G. (1992). *How to untrack your school.* Alexandria, VA: Association for Supervision and Curriculum Development.
This booklet offers a concise guide to untracking schools, including a brief review of the research, a discussion of practical alternatives, an implementation process, and a list of helpful references and resources.

Wheelock, A. (1992). *Crossing the tracks: How "untracking" can save America's schools.* New York: New Press.
This book is a rich source of suggestions for untracking schools. The author provides numerous examples of schools that have untracked and includes countless examples of strategies, tactics, methods, and materials both for implementing a change process and for providing effective instruction in heterogeneous classrooms. In addition to providing documentation regarding effective practices with mixed ability classes, the book captures the excitement that teachers and students feel when they move to inclusive schools. It is highly recommended as a resource and is particularly compelling for readers who are skeptical about both the feasibility and the benefits of untracked schools.

APPENDIX A

Position Statement on Ability Grouping

To ensure educational equity and excellence for all America's youth, NASP supports the creation of inclusive classrooms that are based on the belief that *all* students can learn – a core value of all schools in a democracy. NASP believes that tracking, or whole class ability grouping, is not consistent with that core value.

Extensive research on ability grouping has documented the following negative effects:

- Students with lower ability achieve less in lower track classes than in mixed ability classes;
- Students with higher ability do not achieve more in tracked classes than in mixed ability classes;
- Placing students with lower ability in tracked classrooms reduces self-esteem, with a particularly negative effect on students' sense of their own academic competence;
- Tracking students reduces the likelihood that students placed in lower track classes will choose college preparatory courses;
- Tracking students reduces opportunities to develop relationships among students from other racial, ethnic, and socioeconomic groups and has a negative effect on race relations;
- The placement decision concerning ability grouping is often made very early in a student's school career, is often based on questionable data, and is enduring.

NASP believes that grouping students heterogeneously offers advantages unavailable in schools that track. When implemented appropriately, heterogeneous grouping:

- Gives all students equal access to an enriched curriculum and the highest quality instruction schools have to offer;
- Avoids labeling and stigmatizing students with lower ability;
- Promotes higher expectations for student achievement;
- Reduces in-school segregation based on socioeconomic status, race, gender or ethnicity, or disability;
- Encourages teachers to accommodate individual differences in students' instructional and social needs;
- Enables students to learn from their peers, including students whose background may be very different from their own;
- Emphasizes effort more than ability.

NASP recognizes that heterogeneous grouping will not automatically guarantee *all* students a quality education. "Watering down" the curriculum or "teaching to the middle" will create disadvantages for able students and should be avoided. While NASP believes that all students can benefit from a more challenging curriculum, we also strongly support the development of a curriculum which recognizes and accommodates individual differences in learning styles, abilities, and interests. To be successful, mixed ability grouping must occur within the context of such a curriculum.

NASP also recognizes that heterogeneous classes require instructional and organizational innovations to accommodate a wide range of learners. Such approaches include cooperative learning groups, peer tutors, flexible grouping practices, team teaching, multi-age groupings, and instruction in higher order thinking and problem-solving skills. Where teachers do not currently possess competencies to enable them to work effectively with mixed ability classes, a commitment to further training is essential.

NASP believes that "untracking" schools requires careful planning and collaboration among constituent groups, including teachers, administrators, support personnel, students, and parents. Planned change can best take place using a model that includes the following:

- A steering committee composed of educators, parents, community members and school board representatives whose task is to study grouping practices and make policy recommendations to the school board;
- Local self-study to assess the impact of grouping practices within the school community;
- Wide dissemination of local and national studies of ability grouping effects;
- A board-approved policy statement on grouping for instruction;
- Well-designed staff development that exposes staff to the research, gives them the opportunity to discuss philosophical issues, and provides sufficient training in instructional methods for heterogeneous classes;
- Implementation of a strategic plan that allows for a phase-in process and ensures monitoring, trouble-shooting, and evaluation.

NASP believes that school psychologists can play a central role in helping schools develop appropriate alternatives to tracking. School psychologists have access to research, understand good instructional practices that enhance learning for *all* students, and possess group problem-solving skills that make them valuable as members of steering committees and strategic planning groups and as staff trainers.

School psychologists can contribute to the process of untracking schools by:

- Making research available to administrators and central office personnel;
- Leading informal study groups to explore alternative grouping practices;
- Becoming members of steering committees assembled to study tracking and to develop policy recommendations;
- Participating in strategic planning and staff development to prepare for untracking.

NASP recognizes that schools cannot simply eliminate tracking but must develop viable alternatives. Developing alternatives to tracking will take patience and careful planning. In order for schools to live up to the promise of educating *all* students to become productive citizens of the 21st century, NASP believes these alternatives must be "characterized by fairness and challenge, with equity and excellence equally available to all learners."[1]

Best Practices in Systems Influences on Children's Self-Concept

Marilyn S. Wilson
California State University, Fresno

OVERVIEW

Self-concept is one's perception of self, based on encounters with the environment and guided by maturation. Through our successes and failures and through comparison with others we form conceptions of our own abilities. These self-concepts can influence our willingness to attempt new or challenging tasks or to persevere. We do not develop self-concepts in isolation. For students the environment (e.g., successes and failures and peer comparison) which shapes self-concept exists largely within the school system. Most parents and educators hope for and work towards positive self-concepts for children. Feeling good about oneself is viewed as a prerequisite for self-confidence, risk taking, and good mental health.

This chapter briefly reviews self-concept and social comparison theory and then examines how school systems inadvertently influence children's self-concepts and how school psychologists can work within school systems to evaluate and develop programs that can have positive influences on students' self-concepts. For example, program evaluation might include the effects on self-concept, as well as on academic achievement, of alternative service delivery systems such as mainstreaming, team-teaching, or cooperative learning. School psychologists can develop intervention and prevention programs in which parents are partners with the school. Finally, programs can be implemented in which students with learning and/or behavior problems are the providers rather than the recipients of services, as in cross-age tutoring. If self-concept is partially formed from feedback on behavior, then competent actions which elicit positive feedback should lead to enhanced self-concept.

Theory of Self-Concept

The global construct of self is typically called self-concept or self-worth. Bandura (1986) proposed that self-efficacy, the "self" that combines self-concept with prediction, is composed from mastery experiences, visceral feedback, verbal persuasion, and vicarious experiences. Therefore, programs and practices that help children achieve (mastery experiences) and give them positive feedback (visceral feedback and vicarious experiences) and encouragement (verbal persuasion) promote positive self-concepts.

Personal accomplishment. The principal component of self-efficacy and self-concept is personal accomplishment; for children accomplishments are relative mastery of tasks presented in school, such as learning to read and to do math. An old motto says, "Success breeds success." Curricula and instructional techniques that allow children to master academic building blocks promote positive self-concepts and children who are willing to tackle escalating academic tasks. For children who find academic work difficult and not particularly reinforcing (or reinforced) other activities (e.g., sports, music, art, 4-H) can be available in which the child can succeed, perhaps even shine. Academic programs and extracurricular activities designed and evaluated with children's social-emotional development as a primary goal are examples of systems' influences on self-concept.

Visceral feedback. The second component of self-efficacy is visceral feedback. These are the messages our body gives us to indicate pleasure, pain, anxiety, and so forth. Children exhibiting somatic symptoms may not be happy, confident individuals. Again, the educational environment should be evaluated for conflicts and adverse conditions that may be provoking the physical symptoms.

Verbal persuasion. Verbal persuasion is powerful! Praise and encouragement can stimulate action and accomplishment. The teacher who uses a classroom management system that recognizes and rewards labor and progress has built a tautology. Verbal persuasion may come with a hidden message, for we are complex beings and attributions are linked to feedback. For example, "you're working hard" may lead to an attribution of "I'm not so good at this; I can only do it with lots of effort," while "you're good at this" implies high ability. In our culture, the latter attribution, of high ability, leads to higher self-efficacy than attributions of expended effort (Schunk, 1983, 1985). Parents of Caucasian children are more supportive of this belief that children do well because they are bright; Asian-American parents reinforce effort and believe success is the result of hard work (Stevenson & Lee, 1990). These beliefs and attitudes shape children's self-concepts and expectations regarding effort. Children who seem to feel that if something is hard for them they cannot do it, so why even try, may be reflecting cultural system messages.

Vicarious experiences. The final component proposed by Bandura (1986) is vicarious experiences. We learn by observing others; we also utilize others as standards for evaluating our own performances. Festinger (1954) proposed that social comparison was used to judge self-performance in the absence of objective standards. Schunk (1983) and Bandura (1986) found children to use social comparison to estimate self-efficacy. School is the primary setting for validating academic self-efficacious beliefs through social comparison; the type of class and classmates influence how competent children judge themselves to be. The development of self-concept through evaluation, feedback, comparison, and maturation is briefly reviewed in the next section.

Development of Self-Concept

Self-concept is developed from accomplishments as evaluated by ourselves or others. Small children receive feedback on their successes and their inabilities from the environment and from persons in their environment. The infant practices eye-hand coordination and is rewarded by reaching the desired object; when he or she waves bye-bye, Grandma responds with a wave, hug, or kiss. When the toddler turns the spoon upside down very little reaches the mouth; feedback is swift, direct, and informative. Young children typically see themselves as competent because they are gradually achieving mastery of developmental tasks (Dweck & Elliott, 1983; Harter, 1983). In well-functioning families, preschool children should feel like they are in the mythical Lake Woebeggon where "all the women were beautiful and all the children above average" (Garrison Keillor, *A Prairie Home Companion* radio show).

When children begin school, they leave the security of being judged on and rewarded for progress toward goals all normally developing children generally master and enter a more competitive domain. Self-concept is lowered during the elementary years as feedback from adults is both corrective and evaluative, and as children begin to compare their performance to that of others (Stipek & Daniels, 1988). Children are given grades on their academic work; they may be placed in groups or tracks for certain subjects. These processes allow and force children to compare their assignments and progress to that of their classmates and to evaluate their own abilities. Social comparison for normative purposes develops in the primary grades, around ages 7 to 9 years (Frey & Ruble, 1985). How social comparison is utilized in class or educational grouping practices to impact children's self-concepts will be discussed in the following section.

Due to developmental differences, children may have very different concepts of task difficulty and of their own abilities than adults. Children below the age of 6 years do not differentiate between ability and effort and, therefore, assume tasks on which they succeed are easy and those on which they fail are difficult (Dweck & Bempchat, 1983; Nicholls, 1984). Young children underestimate task difficulty and have unrealistically high expectations of their own ability (Dweck & Elliott, 1983). By 11 or 12 years of age, children can differentiate the parts played by luck, task difficulty, ability, and effort in success or failure (Nicholls, 1984; Stipek, 1988).

BASIC CONSIDERATIONS

The self-concepts of school-age children are molded by the instructional environment and their relative success in school. Students with mild disabilities frequently exacerbate their learning problems by demonstrating an apparent lack of motivation that can lead to less engaged time and result in lower levels of achievement. When students continually meet with failure in academic tasks or see their performance as less competent than other children to whom they are comparing themselves, they often exhibit less perseverance (Schunk, 1983). This eventual lack of effort created and/or fed by lack of success is learned helplessness (Peterson, 1992). Therefore, if setting controls curriculum and curriculum determines the possibility of success, the setting in which children are taught and the ensuing curriculum may designate how students perceive themselves academically.

Within most settings parents and teachers provide the verbal persuasion element of self-efficacy. Children should receive encouragement that, with effort, they can learn. Students respond to praise and reinforcers by continuing to work and to try, and the praise and reinforcers are usually controlled by the adults in their lives. Reinforcers can be offered on an individual basis or through a class management system or be system-wide and involve community resources, as in reading-for-pizza projects. This section examines some of the ways school systems influence children's self-concepts.

Grouping

School systems influence self-concept by the mere fact children are forced into groups at ages in which they are learning to estimate their "worth" by comparing themselves to others. School children are typically placed in classes by age; beyond that the grouping may be heterogeneous or homogeneous. A recent position paper on grouping by the National Association of School Psychologists (NASP, 1993) addresses the academic and emotional influences of homogeneous grouping. Regular education classes are usually heterogeneous; however, regular education students may be grouped within a class for a specific subject (e.g., reading) or between classes by level of the subject matter (e.g., Developmental English, Advanced Placement English). Placement into a special education program constitutes grouping with distinct implications for a student's self-concept. Special education students are usually part of two groups; their regular education peers and their special education class. The proportion of time and influence of each depends on the restrictiveness of the programming (Wilson, 1992). These groupings impel the curriculum, opportunities for mastery, and social comparison processes.

Heterogeneous groups offer confounds in curricula and self-concept results; the curriculum may be inappropriate for slower and brighter students. Social comparison theory predicts negative effects on self-concepts of slower students and positive effects for the gifted in the heterogeneous groups (see Figure 1). It is frequently argued that in heterogeneous groups slower students are provided with role models of more competent students. However, through social comparison slower students will view themselves as less competent. Ego-wise, good students can see themselves as very competent in a heterogeneous group (Kulik & Kulik, 1991).

A grade-level class is usually heterogeneous with a middle-of-the-road curricula. Slower students struggle and the brighter students are bored. To present a broader range of curricula and better match students' achievement levels, sometimes a leveled or tracked curriculum is offered within the class or between classes. With homogeneous grouping and appropriate curriculum, the slower students may be better able to master the material and the brighter students challenged. In homogeneous groups the slower students can compare themselves favorably to others in the group; however, they may suffer loss of esteem due to the lower status of the group. In gifted classes brighter students are now part of an elite group, but suddenly may find themselves as only equal or even "dumber" than others in their group.

The recent NASP position paper on grouping (1993) adopted a position endorsing heterogeneous classes. However, there is no one result of grouping on self-concept; the forces of curriculum, group membership, and social comparison oppose each other. For gifted students the "big frog in a little pond" effect can allow for a generous self-concept in a heterogeneous class, even if the curriculum moves a little slowly (Bachman & O'Malley, 1986). On the other hand, with the challenging curriculum and status of advanced placement of talented and gifted classes, comes the position of being an equal, or perhaps slightly less competent, student than the others in the group. The reverse is true for slower students; they are allowed a more manageable curriculum and similar peers in return for the stigma of special education placement.

Retention

The academic gains of retention are generally not large nor long lasting (see the chapter in this book on retention), but the effects on self-concept can be devastating. Negative effects have been found to social and emotional adjustment and to self-concept regardless of the age at which the child was retained (Holmes & Matthews, 1984). Students view retention as punishment and a sign of failure (Smith & Shepard, 1989). In addition, they are removed from their same-age peers and classmates. Following retention, students may receive failure feedback from parents, peers, and teachers.

Some children are retained prior to starting school. "Red-shirting" kindergartners (as with football players) so they will be older — for academic, athletic, or social reasons — amounts to retention before they even begin! Longitudinal evidence suggests few academic benefits to this practice nor for transition programs which provide for a developmental year between kindergarten and first grade (Dawson, Raforth, & Carey, 1990). If children have assumed they would start school with their preschool friends or peers, staying home or in preschool (or kindergarten) another year can be quite disappointing and result in feelings of failure, incompetence, and lower self-esteem unless handled very carefully.

Special Education Placement

Special education placement may combine the worst of both retention and low-status grouping. In fact, many of these children have already been retained before being placed in special education. The literature previously reviewed discussed the impact on self-concept of placement into a homogeneous, lower functioning group. Placement into special education may, at last, allow the student a manageable, functional, and appropriate curriculum, but at the price of the special education label and membership in a lower status group. Extensive research indicates that special education students view themselves as academically less competent than their peers (Bear, Cleaver, & Proctor, 1991; Renick & Harter, 1989).

Spending years in special education can exacerbate feelings of worthlessness. Because of slow progress the curriculum tends to be exceedingly redundant: year after year of Individualized Educational Program (IEP) goals on reading and spelling, years of minimal growth and little concrete evidence

FIGURE 1. Relationship of grouping and self-concept.

ABILITY	VARIABLES	HOMOGENEOUS GROUPING	HETEROGENEOUS GROUPING
Brighter Students	Curriculum Social Comparison Group Membership	Challenging Curriculum Equal or Upward Social Comparison = Lower Self-Concepts Membership in Elite Group = Higher Self-Concept	Bored by Curriculum Downward Social Comparison = Higher Self-Concept
Slower Students	Curriculum Social Comparison Group Membership	Manageable Curriculum Equal Social Comparison = Higher Self-Concept Membership in Lower Status Group = Lower Self-Concept	Frustrated by Curriculum Upward Social Comparison = Lower Self-Concept

of such. As students enter junior high and high school, the curriculum diverges and becomes vocational; there really is no going back for students in a special class. And unless carefully couched in encouragement both at home and school, a work-ability program is not going to be viewed as prestigiously as college preparation courses. Ways to make curriculum feedback more beneficial to self-concept will be presented in the Best Practices section.

Attributions re Parental and Teacher Feedback

Children can interpret comments and actions from adults in various ways and become discouraged, timid, or embarrassed. Brophy (1983) reviewed the effects of teacher praise on children's self-concepts. Teacher expectations can become self-fulfilling prophecies; expectations can be conveyed to students through praise for low effort or incorrect responses or less feedback and attention. Does the mainstreamed child participate in class or is she or he "just there?" Children who need help most in classes may be least likely to ask for it because they do not want to be noticed or perceived as incapable (Jenkins & Heinen, 1989). Receiving unsolicited help from the teacher may be even worse, for children then make causal inferences of low ability (Aberbach & Lynch, 1991). "If I can't figure this out by myself, I must be dumb/" "Is anyone else getting help?"

Parents can provide academic assistance so their children can do better in school and feel more confident and offer positive reinforcement for effort and achievement both at home and school (see Christensen & Conoley, 1992). Dunst and Trivette (1987) discuss models of enabling and empowering families and conclude that a compensatory model in which parents are seen with limited responsibility for their history but primarily responsible for their future best promotes self-efficacy among parents.

School psychologists can provide research for decision making and evaluate the social-emotional aspects of instructional environments and programs as well as develop training programs for parents and teachers and prevention programs for students. The first step is awareness of system decisions and practices on students' self-concept.

BEST PRACTICES

Psychologists and mental health consultants for school-age children are involved in the promotion of good mental health. As interventionists or as program evaluators, school psychologists can be involved in working toward better self-concepts for students (individual assessment and intervention for children with low self-esteem is covered in a separate chapter in this volume). School psychologists can serve as advocates for children in decision-making processes regarding appropriate educational and developmental programs as well as present research, both national and local, on the efficacy of such programs and practices. Lastly, school psychologists can assist or lead schools in developing programs and practices that enhance children's self-concepts (see Figure 2).

School Psychologist as Child Advocate

As a child advocate, the school psychologist can

- Participate in evaluating which program and which curriculum within a program provides maximum chances for success, academically and social-emotionally.
- With the program decided on, discuss ways the student's self-concept can be enhanced.

Decision making. Meetings where decisions are being made should perhaps begin with the warning that special education placement and/or retention can be hazardous to children's mental health. Concern over the stigma of labeling accompanied PL 94-142 (Hobbs, 1975). Litigation regarding test bias and overrepresentation of minority children in special education classes has been predicated by the assumption that placement in a special education program is detrimental socially and emotionally via lower self-esteem and that this supersedes academic benefits (Prasse & Reschly, 1986). Retention has been found to result in lowered self-esteem for many children. Obviously, it is not advocated that no students be placed in special education nor retained. But the school psychologist is generally the member of the multidisciplinary team best qualified to make recommendations on the relative benefits and anticipated problems for a particular child.

According to the NASP Position Statement on Student Retention (1988), the best candidates for retention are children with minor academic deficits due to lack of instructional opportunities, such as illness, and with high self-concepts and good social skills. However, it is cautioned that the predictability for individual cases is low: There is no way of knowing which few children will benefit from repeating a grade. The school psychologist can point out research supporting individualized instruction and the evidence that retention does *not* help exceptional children nor prevent special education placement at a later date. In this case the child's ego has received a double whammy; these are not decisions to be made lightly.

Curriculum. Curriculum is as linked to special education programs as is image. As students remain in special education programs or are placed in more restrictive options the split between the regular classroom and special education curricula widens. Young children with minor academic deficits may, indeed, "be remediated" and soon returned to or, for the most part, remain in regular education classes. Those with more serious learning or behavior problems may be embarking on a path that steadily narrows. Especially in junior and senior high school, course content in special classes is largely prevocational. As members of IEP teams, school psychologists need to urge teachers, students, and parents to develop goals that result in a functional and meaningful curricula and that teach and reinforce responsibility and independence. These characteristics are necessary for self-respect and employability; being able to get and hold a job is vital to self-esteem as an adult.

When sitting around the table making decisions about the most appropriate educational program for young children, the school team needs to take a long look at the future and picture where this youngster might be — and what program maximizes his or her potential. Are the parents aware of the curricular and social-emotional implications of the decision to be made? Has a fair presentation been made of the literature on placement and retention, the local school programs and options, and likely outcomes for this student? Once a decision has been made, strategies should be developed to promote healthy adjustment and self-concepts. Strategies that transcend educational borders and can be utilized within both regular and special education programs include home–school communication, frequent feedback, and student participation in goal setting.

Home–school notes. Home–school notes are used to assist parents and teachers to work as a team to support the student (see Kelley, 1990). This communication can be designed to encourage parents to praise and reinforce their child for success in school. Goals on home–school notes frequently focus on personal responsibility and work habits, precursors to successful employability and the concomitant satisfaction of being able to support oneself. Children are not expected to subscribe to such far away goals; they feel good *now* when their work and efforts are recognized.

A home–school note is really a contract between the parent and student which is facilitated by the teacher. Goals that focus on academic, study, or behavioral needs are established and objectively defined. Remember how self-efficacy was described as composed of mastery experiences, psychological states, verbal persuasion, and vicarious experiences? Home–school notes should be construed to provide verbal persuasion (praise) for mastery experiences; for that to occur the target behaviors must be reasonably obtainable. Collect data on a peer; gather baseline data for the target student. How often do other students perform the behavior; what was the rate of performance for this student? Peer data is useful for setting an aim line; use baseline data and decide what is reasonable to expect now. Set the goals low enough to be readily achievable at first; the child must obtain the reward for it to become reinforcing. Failure and recriminations are not going to improve self-concept.

Curriculum-based measurement. A similar philosophy should be followed for academic goals. Success — with some effort — builds self-concept and promotes self-efficacy. Curriculum-based measurement (CBM) is an excellent way to determine the level of curriculum that is attainable and a slight challenge (see Shapiro, 1989; Shinn, 1988). Baseline data can indicate where the student is, schoolwide norming provides local standards to determine where to set the aim line, and progress monitoring offers frequent feedback. It is both motivating and reinforcing to know on a regular and frequent basis how you are progressing. The most convenient way to provide this is with a computerized curriculum-based program (see Fuchs, 1986).

Computerized CBM sets individual goals, provides practices, monitors progress, and gives feedback via graphs on the screen. School psychologists can remind teachers of the motivational and educational aspects of frequent monitoring and train them to construct probes, gather data, develop norms, monitor progress, and make instructional change decisions. It is most efficient if CBM is adopted as part of system reform because of the need for administrative support for training and norming and the construction of materials.

Class spelling tests and other drill materials can also be individually graphed to provide information on growth. The efficacy of these programs was demonstrated by Pavchinski, Evans, and Bostow (1989). Students participated in daily drills on math or reading. They were given tokens for correct answers within a set period of time, and made to engage in positive practice to correct incorrect responses. Students found the plan enjoyable and made good academic progress.

As child advocates, school psychologists need to consider the best interests of the whole child in program decisions. Placement in special education or retention directly influences self-concept via stigma and indirectly through the curriculum and social comparison. Feedback and positive reinforcers can be provided with CBM and home–school communication interventions. CBM and behavioral strategies can be incorporated into school restructuring.

Role of the School Psychologist in Program Evaluation

School psychologists have the training to assist schools in program evaluation. Program evaluation related to students' self-concepts includes the effectiveness and efficacy of special education, mainstreaming, cooperative learning, and curricula. Special education efficacy has been criticized and alternative service delivery models proposed, for example, team teaching of regular and special education students or the special education teacher coming into the regular education classroom to work with special education and other low-achieving students.

Mainstreaming/team teaching. When looking at where best to serve students in need of extra assistance, the school team might consider student preferences as well as program efficacy. Jenkins and Heinin (1989) and Wilson (1992) found students to prefer to leave the regular classroom to obtain extra help rather than have the special classroom teacher come into their classroom. Reasons included embarrassment, convenience for the teacher, and "like to leave the classroom." Other possible explanations for this unexpected result are attention from the special teacher and more familiarity with the pullout model than team-teaching. The school psychologist could encourage caution and data collection on children's preferences and self-concepts if changes are planned for instructional models. Research on alternative systems needs to consider how children feel about themselves in various settings. The following letter was printed in the May 1993 *Communiqué:*

> Dear Mainstream Students:
>
> We would like to share with you our experiences in special education. We would like to let you know

> what we like and do not like about being special ed. students. We hope that by giving you this information, you will understand us better.
>
> These are some of the reasons why we like being special ed students:
>
> 1. Learning is geared to our pace.
> 2. Classroom sizes are smaller, so we get extra attention from the teachers.
> 3. Material is explained so that we understand it.
>
> These are the disadvantages of being a special ed student:
>
> 1. Mainstream kids tease us, and
> 2. They make us feel badly about ourselves.
>
> We hope this helps you understand us better and please know that we are not so different from you after all. (Betensky, 1993, p. 22)

While team teaching is a recent innovation, mainstreaming of students with special needs into regular classrooms has sufficient history for several empirical studies on self-concept of students in regular and special classes who are learning disabled and mildly mentally disabled (Madden & Slavin, 1983; Meisels, 1986). Lower academic self-concepts have usually been found in the mainstreamed settings; no differences were reported for social domains. The psychological construct of social comparison probably accounts for these findings. Students with learning problems are making comparisons with other mildly disabled students in special education classrooms, but comparing to regular education students in mainstreamed classes. Research over the past decade suggests ways to ameliorate social comparison. MacIver (1987) found students who received frequent grades were less likely to engage in social comparison. Rosenholtz and Rosenholtz (1982) also found the students with individualized assignments were less able to compare and evaluate on the basis of social comparison, and thus most saw themselves as very competent.

Curriculum, grouping, grading, and reports are educational practices in which the school psychologist can work with the school personnel to evaluate which methods or strategies optimize both achievement and self-concept. When students are working in individualized curriculum with individualized goals, the ability or need to compare is mitigated and children feel good about their own successes and progress, without making classwide comparisons. We currently have the technology with curriculum-based measurement to provide more individualized programs for students and possibly eliminate the detrimental effects of social comparison in mainstreaming. Children are mainstreamed to learn together, not to compete. Cooperative learning is another technique that appears to be good for children.

Cooperative learning. According to Madden and Slavin (1983), mainstreamed students need maximum contact with nondisabled peers, prefer not to be identified or singled out, and do best in a noncompetitive atmosphere. Cooperative learning can provide all this.

Cooperative goal structures have been found by Johnson and Johnson (1986) to promote positive self-concepts. Students feel good because they are part of the success of the group. However, the group must be structured so lower achieving students can feel they are making a contribution. The positive peer evaluations found in cooperative settings are very influential in promoting self-esteem. Overall, cooperative learning environments are (mentally) healthier compared to competitive environments.

Mainstreaming students with learning difficulties into the regular education classroom poses threats to self-esteem, mostly due to the embarrassment of doing worse than peers and of needing extra help. These problems can be minimized if help from special teachers is provided to a number of students who need assistance, regardless of special education status. Secondly, individualized curricula diminish the need and ability to make comparisons. Cooperative learning enhances self-concept by allowing all students to contribute and receive positive feedback.

Opportunities for School Psychologists in Program Development

Epstein and Dauber (1991) encourage school psychologists to take on the role of mental health psychologist for the school. As part of that role, increased involvement with the emotional well-being of all students is implied. Development or implementation of new programs may be required to maximize ways to enhance student self-esteem. Examples could include peer tutoring, buddy systems, parent education, and community-school programs.

Peer programs. Self-concept is enhanced if students feel competent about something they are doing. Peer programs allow students to work within areas of strength and earn the satisfaction of being the teacher — the giver — instead of always the needy recipient. Peer tutoring programs offer advantages to tutor and tutee. The tutee learns with extra practice opportunities in a social environment. The tutor has a chance to shine and feel good about helping. For many children the best opportunities are working with younger children. They can read to them, work with flash cards, or show them how to play a game. Regardless of the task, it is very rewarding to be the teacher! Being a buddy for a mainstreamed student with more severe disabilities is another area where mildly disabled students can become leaders. They can facilitate social interactions and assist with routines; working with others is an excellent way to build self-confidence and skills.

Parent training. Psychologists can also develop parent training programs to help parents learn how to work with and support their children. Research indicates parents are more involved in elementary than middle schools, and in self-contained classrooms rather than departmental (Epstein & Dauber, 1991). Communication is the most prevalent type of activity; home-learning the least (Epstein & Dauber, 1991). Programs for parents can be implemented that allow for ongoing, meaningful participation of parents in the educational programs of their children. According to Cochran and Dean (1991), "empowerment is a process rather than an end state" (p. 262). Based on almost 3 years of research on a program of family support, they found parents' self-concepts improved as well as their relationships with others in the family. Some groups focused on improving the neighborhood; other parents got involved in their children's school. The emphasis of the home-visit program was that parents were the most important influence in their child's life, and children whose parents were involved in the program were doing better in first grade than a control group.

Teachers involved in home-school programs report increase self-efficacy, possibly due to the fact they are more highly rated by parents who participate in the programs. Increased communication serves to improve the self-concepts of both parties. School psychologists are in an excellent position to facilitate communication between teachers and parents through collaborative consultation. School psychologists can emphasize benefits to all from a coordinated program focusing on child strengths and needs.

To start a home-school program the partners in education need to envision their school of the future and determine a plan and practices. Research is necessary to evaluate the efficacy and worthiness of a program. The members need to be committed to listening to parental concerns and feelings as well as reviewing empirical evidence of support and change. Finally, a school-community program needs leadership and vision by those who do believe that all children can learn and that sharing the responsibility improves the odds of that happening.

Community programs. Student pride and self-concept is increased when their culture is endorsed by the system. Don Davies of Boston University (1991) described a demonstration project for school and community interactions called "Schools Reaching Out." Workable components included (a) a parent center; (b) home visitors, and (c) research teams of teachers. The parent center was a place for parents to meet in the school, participate in English-as-second-language (ESL), and General Education Development (GED) classes, organize volunteer activities for both working in school classes and assisting other parents in need of social or health services. The parent center was staffed by two paid parent coordinators and equipped with a telephone and a coffee pot.

Most parents want their children to do well in school but may not have skills to assist them with their learning or in managing their behavior. The home visitors were recruited from the community and trained to provide information, materials, and support. They each visited four to five families per week and were paid $10 per hour. Davies suggests Chapter I money as one source of funding and that training for the visitors might be provided by local universities (school psychology program trainers?).

An old African saying points out the shared responsibility schools, families, and community agencies have for raising children: "The whole village educates the child." Schools and children in rural communities often benefit from enormous community; the school is viewed as the social center of the town and school activities as vital events. Students bask in the care, concern, and encouragement of many members of the community outside their immediate or extended families. These are people who offer congratulations and summer jobs; who pitch in when a family suffers a crisis and let the members know they are important; and who provide comprehensive monitoring of the behavior of the town's young people, often to their dismay. Urban families battling poverty, unemployment, and language barriers particularly need the support of their communities. Schools, parents, students, and community agencies and businesses can work together to set up programs to prevent drugs and dropping out. Self-concept is improved both by knowing someone cares and by participating in positive actions.

Similarly, just as younger students can achieve an enhanced self-image by helping others through peer tutoring programs, secondary students involved in community service programs such as cleaning up graffiti or volunteering as a candystriper or in a nursing home have the satisfaction of providing meaningful service. Psychologists can provide a mental health perspective: Activities of this type not only develop skills and provide needed services, but through sharing students grow in self-respect.

Psychologists and counselors working in secondary settings can assist schools in finding local employment training positions for students in vocational programs, including lower achieving and special education students. Self-efficacy is based on prior achievements; what better personal predictor for future success than mastering the technical and interpersonal skills necessary to hold a workability job.

SUMMARY

Although school psychologists are mental health practitioners, most of school psychology work has focused on assessment and promotion of academic and social skills. This chapter discusses school psychology services and system influences from the perspective of student self-concept. Practices frequently engaged in, placement in special education and readiness/retention decisions, have grave implications for self-concept. School psychologists are in a position to advise multidisciplinary teams of research findings regarding short- and long-term effects of these practices on the child's academic progress and emotional well being.

Within the school system traditional methods of grouping and curriculum also influence how students perceive themselves. Program evaluation should include social-emotional, as well as academic, outcomes. Alternative service delivery systems, for example mainstreaming and team teaching, have also been found to be detrimental to student self-concept under certain conditions. Individualized curriculum and cooperative learning were suggested as two system-level reforms to reduce social comparison and increase self-concept.

Parents are also recognized as powerful influences on children's self-concepts. Parents can work with school personnel (a) to help their children improve their performance and thereby earn more internal and external positive feedback and (b) to provide recognition and reinforcement for achievement. Finally, communities can have an important role in supporting families. Through volunteer and service programs, students can increase prevocational skills, provide services to those in need, and learn responsibility and self-respect. Most of the activities, programs, and practices presented in this chapter are normally utilized to increase academic skills and that may be a sufficient reason to implement a program. However, competencies will be most wisely and energetically used by confident, mentally healthy children and adults. School psychologists should lead the development of practices to enhance the self-concept of the students with whom they work.

Best Practices in Substance Abuse Prevention Programs

Kathleen M. McNamara
Cleveland State University

OVERVIEW

The Need for School-Based Prevention Programs

The problem of alcohol and other drug (AOD) use among American youth is illustrated by results of The National Household Survey on Drug Abuse conducted by the National Institute on Drug Abuse (NIDA). This 1990 survey found that 48% of youth aged 12 to 17 had used alcohol, with 41% reporting use in the previous year and nearly one-quarter reporting use in the previous month (NIDA, 1990). Experience with illicit drug use was reported by 22.7% of this group.

According to NIDA's National High School Senior Drug Use Survey conducted in 1990, 47% of participating seniors reported past use of one or more illicit drugs, while 80.6% reported past use of alcohol (NIDA, 1991). Almost one-third of participating seniors reported having five or more drinks during a single drinking occasion within the preceding 2 weeks!

These statistics reflect only part of the problem, however, because the measures were limited by the voluntary and self-report nature of surveys. In addition, school dropouts and absentees, who are likely to be more heavily involved in AOD use, were not even represented in the National High School Senior Drug Use Survey.

The anti-drug-and-alcohol-abuse efforts spearheaded in recent years by federal, state, community, and private agencies have had a positive impact on this problem. However, although the nature of abused substances and patterns of use have changed among certain groups in the past decade, overall levels of AOD use and abuse are still unacceptably high, particularly among the youth served in our nation's schools.

Title V of the Elementary and Secondary Education Act (1988) fostered widespread acceptance of the notion that schools are an appropriate forum for prevention and intervention efforts. In addition to their role as a primary vehicle for transmitting academic, vocational, and civic knowledge and skills, schools have assumed increasingly greater responsibility for addressing a variety of problem behaviors and social concerns. In discussing preventive programming in schools, Milgram and Griffin observed that "the role of the school . . . is not a choice of action or inaction, but rather a choice of acting purposefully and systematically, or sporadically and inconsistently" (1986, p. 16). Clearly, schools have significant potential for impact on the AOD problem because they not only afford ready access to educational resources and expertise but also house the population requiring accurate information and guidance in making choices about use.

This chapter offers a model for comprehensive school-based prevention programs based on consideration of four principal prevention methods as applied to three distinct audiences in the school population.

Prevention Programs: Methods and Audiences

Alcohol and other drug abuse prevention may be viewed as comprising a matrix of four methods, each directed toward three audiences in the school population.

School *policy* initiatives are reflected in written documents developed by or for local education agencies, setting forth a statement of philosophy about AOD use, supported by a set of rules, administrative procedures, and consequences for rule violations. Policies often include a description of the school's comprehensive program for AOD prevention and intervention activities.

The second method, *education*, is prominent in school programs, particularly since the passage of Title V of the Elementary and Secondary Education Act (1988). The method of education includes the dissemination of information about the harmful effects of AOD use as well as instruction in skills promoting social competence, especially resistance to cultural pressure to use alcohol and other drugs. Education also includes awareness campaigns, such as the National Red Ribbon Celebration, which solicits broadly-based support for drug-free lifestyles.

The method of *alternatives* encourages students to engage in activities incompatible with AOD use. Commonly, schools offer open gym nights or sponsor alcohol- and drug-free prom and graduation activities. In recent years, the method of alternatives has been expanded to include efforts to promote "positive peer culture" and methods to engage students in schools as a protective force against AOD use.

Finally, *intervention, treatment, and support* methods, as implemented in schools, consist of preliminary identification, assessment, and referral of students whose behavior places them at risk for involvement with alcohol and other drugs. These methods also include support groups for at-risk students as well as those recovering from diagnosed AOD dependency.

Audiences for Prevention Programs

It is helpful to regard a school's student population in terms of three audiences, each reflecting a level of prevention. The *primary prevention* audience consists of those who have not yet used alcohol or other drugs. For this audience, prevention activities are designed to "either reduce the rate of occurrence or a particular problem, or strengthen the well-being of the individuals in the population as a form of inoculation against the causes of subsequent problems" (Pianta, 1990, p. 306–307).

The *secondary prevention* audience consists of students who are at high risk for AOD use. Secondary prevention activities are designed to interrupt, minimize, or protect against the influence of these risk factors, with the goal of reducing the likelihood of AOD involvement.

Finally, the *tertiary prevention* audience consists of those who have already engaged in AOD use. Experience in the schools shows substantial diversity in this audience, ranging from students whose use is experimental in nature, through those with regular patterns of use, to those whose use is of a dependent or addictive nature. The last group is further subdivided into those whose addiction has not yet been identified or treated and those who are in the process of recovery from addiction. The purpose of tertiary prevention is to reduce the adverse consequences of any level of AOD use through appropriate intervention and treatment activities.

Prevention methods are most effective when there is an appropriate "fit" between their message and the characteristics of their audiences in the school population. While an awareness campaign may be helpful in reducing the incidence of early first use of alcohol and other drugs, it is not likely to have an impact on students who are already engaged in regular use. Similarly, an educational program which features the testimony of a young adult or successful athlete recovering from addiction is not likely to address the needs of students who have never used drugs (and may, in fact, inadvertently promote such use) — although it may be effective with students who have entered a dangerous phase of regular use.

BASIC CONSIDERATIONS

A research-literature base for AOD prevention efforts that can serve as a resource for program design has only recently begun to develop. Throughout the 1980s, and particularly with the passage of the Drug Free Schools and Communities Act of 1986, schools were inundated with promotional literature for AOD prevention curricula and training programs. Recognizing the need to address the growing problem of AOD use, schools adopted programs despite a lack of validation of their effectiveness in actually reducing and eliminating AOD use. Programs commonly lacked an adequate evaluation component or failed to evaluate AOD use as a specific outcome measure. At present, in part because of funding provisions that specify program components and evaluation, the prevention field is undergoing a period of transformation. While the research has not yet yielded conclusive data to form guidelines for program design, there is a growing knowledge base which should serve as the basis for prevention efforts.

This knowledge base provides information about circumstances, characteristics, and events that place youth at greater risk for AOD involvement as well as those that appear to exert a protective influence. School-based programs seek to reduce or mitigate risk, while promoting protection, through activities with demonstrated potential for effectiveness. This section explores this knowledge base, considering research findings on risk, protection, and program effectiveness.

Knowledge Base: Audiences for Prevention Programs

Traditionally, school-based prevention programs have focused on the variable of AOD use or non-use. Policy, education, alternatives, and intervention activities were narrowly focused on the goal of reducing and eliminating use among adolescents.

In recent years, however, research has demonstrated that experimental AOD use, while undesirable, may nevertheless represent an aspect of normative adolescent development (Shedler & Block, 1990). In addition, research has increasingly focused on factors (identifiable in the early school years) associated with increased *risk* for AOD use as well as factors associated with a decreased likelihood of use. Very recently, researchers have also identified differences in factors contributing to levels of use, observing that factors contributing to initial and experimental use differ from those associated with escalations in use.

Risk factors. Research on factors associated with the initiation of AOD use has yielded extensive support for a number of correlates, including easy availability of illicit substances, disadvantaged socioeconomic status, lack of religious commitment, poor school performance, rebelliousness and lack of conformity with laws and norms, perceived adult drug use, low self-esteem, impulsivity, sensation-seeking, many deviant behaviors, poor and inconsistent family management practices, association with drug-using peers, and low commitment to school (Clayton, 1992; Newcomb & Felix-Ortiz, 1992). These factors place students at risk by creating a state of vulnerability or susceptibility to AOD use.

Glantz (1992), summarizing longitudinal research studies on risk, notes that, at age 7, future frequent AOD users were "unable to form good relationships, were insecure with evidence of low self-esteem, manifested numerous signs of emotional distress, which they denied, and had poor coping, adapting, and interpersonal problem solving skills" (p. 408). In late childhood, these characteristics were exacerbated, expressing themselves in poor school achievement and peer group integration, maladaptive problem solving and coping skills, affiliation with deviant peer groups, and proneness to behavior problems. Family problems and stresses, in addition to parent or sibling models of drug use, take on increased salience.

Austin (1992) argues for the importance of school failure factors as common precursors or antecedents of the initiation and escalation of AOD use. In reviewing research on correlates of AOD use, he observes that, while school failure factors do not have as strong or as direct an influence in AOD use as peer associations, they are often embedded in a developmental history characterized by disengagement and the adoption of unconventional behaviors. Patterns of school failure can be identified as early as second grade; Slavin and Madden (1987) note that, by fifth grade, many students are caught up in a permanent cycle of falling behind and remediation. Summarizing the relationship between school failure and AOD use, Austin concludes that "youth who are failing at school by mid-adolescence, and facing a bleak future, are likely to see little reason why they shouldn't use drugs and to have little motivation to resist pro-use messages" (1992, p. 25).

Glantz notes that high-risk children are less likely to be influenced by protective factors, and, because they have been unsuccessful in developing adequate coping skills and strategies, these skills are "generally less available in (their) repertoire even if the maladaptive ones are successfully discouraged from use" (1992, p. 409). As a result, vulnerability to AOD abuse is often well-established by the onset of adolescence. Recent research has demonstrated that factors associated with initiation differ substantially from those associated with escalation of use. Survey data indicate a high prevalence of experimental AOD use among students. Therefore, the nature of factors promoting *escalation* of AOD use requires special attention. It is important to identify and intervene on those factors associated with escalation.

For example, individuals whose initial AOD use results in negative social sanctions tend to escalate use. Those who label AOD use as deviant are also more likely to escalate levels of use. Males whose initial AOD use arises from a motivation to express anger or increase potency are likely to escalate use, as are females whose AOD use is intended to cope with disrupted relationships (Kaplan & Johnson, 1992). These findings, some of which contradict commonsense notions of the motives underlying AOD use, represent critical information for programs addressing the needs of the tertiary prevention audience.

Some risk factors, such as academic failure, are amenable to direct intervention efforts. Others, including environmental circumstances, are not amenable to direct intervention. For the latter group, intervention efforts generally focus on the introduction of protective factors to buffer the influence of the risk factor, thereby reducing the likelihood that it will lead to AOD use or abuse (Clayton, 1992).

Protective factors. Relative to research on risk factors, the literature on factors that protect against AOD use is sparse and inconclusive. McIntyre, White, and Yoast (1990) observe that "among the researchers using a risk paradigm, protection against substance abuse is greatly overshadowed by the clamor to identify risk factors. And when protective factors are discussed, it is often with the assumption that they are the opposite of risk factors, hardly a sophisticated analysis, and perhaps even wrong" (p. 23). The authors further caution against confusing protective factors and interventions, noting that laws and sanctions, which may reduce AOD use, represent interventions, not protective factors. They also note that a factor which is protective against problems in some behavioral domains may create risk in other domains.

Research has failed to demonstrate a conclusive relationship between academic failure or success and later AOD use. However, Austin (1992) noted that, while academic problems in the early years of school may not be predictive of later AOD use in the general student population, "school success may play an important protective role among those youth who are *otherwise at high risk* for AOD abuse" (p, 19, emphasis added). Furthermore, the potency of academic success as a *mitigator* of early risk factors demonstrates that the negative impact of risk factors can be ameliorated by protective factors emerging later in the child's experience. It is, therefore, essential to approach the emerging literature on protective factors with an appreciation for their complexity.

Protective factors include individual attributes or characteristics, as well as situational or environmental conditions that inhibit, reduce, or buffer the probability of AOD use or escalation of use. Their protective influence is often observed in interactions among several factors. For example, Brook, Cohen, Whiteman, and Gordon (1992) demonstrated that low childhood aggression, interacting with low peer deviance and low peer illegal AOD use, yields conditions which are protective in nature. The role of protective factors in discouraging AOD use is by no means clear. Other research demonstrates that certain factors, such as school success, may play a protective role for students who are otherwise at high risk, although they may not have a significant role as a predictor of abstinence in the general student population (Austin, 1992).

Attachment with significant adults (particularly parents), expressed in support, communication, responsiveness, affection, and identification with the adult, serves as a deterrent to AOD use (Brook, Brook, Gordon, Whiteman, & Cohen, 1990). Other protective factors identified by research include high levels of educational aspiration, high grade point average, low depression, high religiosity, internal locus of control, personal and social competence, high self-acceptance, effective coping skills, autonomy, positive social bonding with institutions, accurate perception of peers' AOD use, commitment to conventional societal norms, and high law abidance. Ecological conditions that deter use, and are therefore often viewed as protective in nature, include communicated and enforced family norms regarding AOD use, effective family management skills and greater family cohesion and intactness, parental disapproval of alcohol and other drugs, discouragement of AOD use by the community, low availability of illicit substances, and the presence of sanctions against use (McIntyre et al., 1990; Newcomb, 1992; Newcomb & Felix-Ortiz, 1992).

Knowledge Base: Effective Programs

Several sources have described common approaches to AOD prevention during the past two decades. *Information-dissemination* approaches convey information about alcohol and other drugs, including their harmful effects. Fear-arousal messages, moralizing, and objective information-giving are included under this category. Anderson (1988) described fear-arousal messages as ineffective because the everyday experiences of their audience (students) failed to support their veracity: "The mere use of drugs did not lead to the problems their elders predicted" (p. 2). Anderson further noted that objective information-giving sometimes had an unforeseen effect: It reduced many students' anxiety about using by providing accurate information about alcohol and other drugs, thereby increasing use levels; further, it was based on false assumptions: "that drug use is primarily a cognitively-based phenomenon, that kids use drugs because they don't know something, and that cognitive knowledge alone is preventive" (p. 3). Despite their intuitive appeal, information-dissemination approaches have been found to have little or no impact on actual or intended AOD use among students (Botvin & Dusenberry, 1989).

A second major AOD prevention approach is *affective education*, which emerged in the 1970s as a result of research showing correlations between drug use and social competencies. Without directly addressing the topic of AOD use, affective education programs focused on interpersonal and intrapersonal competence and environmental responsiveness to the emotional, social, and cognitive needs of children. Austin (1992), reviewing research on the effectiveness of affective education programs, concluded that "these programs did not result in any meaningful reductions in use and in some cases may have contributed to increasing it" (p. 26).

It has been hypothesized that the failure of affective education as an effective AOD prevention strategy lies in the absence of a clear focus in such programs, inadequacy in the number and frequency of interventions, and application of inappropriate methods for fostering skill acquisition among students (Austin, 1992; Botvin & Dusenberry, 1989).

In response to these criticisms, a third category of preventive programs evolved, aimed at the development of social competence through *skill-training*. Early versions of this approach were designed to "increase students' awareness of the various social influences to engage in substance use along with specific resistance skills for effectively coping with these negative influences" (Botvin & Dusenberry, 1989). Students are taught to recognize and respond to high-risk situations with refusal techniques. A key feature of these programs is their emphasis on specific skills, taught through modeling, rehearsal, and reinforcement. The Prepare Curriculum (Goldstein, 1988) and Skillstreaming approach (Goldstein, Sprafkin, Gershaw, & Klein, 1980; McGinnis & Goldstein, 1984) provide examples of skill-training models that have been applied in AOD prevention programs. Project SMART, or Self Management and Resistance Training (Hansen et al., 1988) uses peer leaders to teach students methods to resist pressures to use alcohol and other drugs, providing opportunities for modeling and practice of skills. It emphasizes intervention on external factors, such as peer and media pressure, negative parental influences, and normative expectations.

Other versions of the skill-training approach are more comprehensive in nature. The Life Skills Training program developed by Gilbert Botvin (1989; 1990), for example, incorporates an AOD-specific component (information on AOD use and abuse, social pressures to use, and techniques for resisting pressures to use), a personal skills component (building critical-thinking, decision-making, and anxiety-reduction skills), and a social skills component (communication, assertiveness, and relationship skills). The Life Skills Training curriculum has three levels which are generally offered in successive years to young adolescents. Project STAR (Student Taught Awareness and Resistance) is an example of a comprehensive, community-based program, representing a collaborative effort between researchers and the community (Pentz, Cormack, Flay, Hansen, & Johnson, 1986). This program, incorporating direct training of youth in resistance skills; training of teachers, parents, and other implementors; and ongoing support for youth and program implementors, serves as a model for uniting school, family, media, and community organizations in skill training and support activities.

Summarizing research on competence-building programs, McIntyre, White, and Yoast (1990) note that they hold promise for enhancing AOD protective factors but have been used primarily with white, middle-class audiences in grades six through nine and been the subject of only limited longitudinal studies of program impact beyond immediate and short-term effects.

Austin (1992) cited the most persistent criticism of programs as their failure to address the needs of high-risk youth. "This lack of success if rooted, in part, to the failure of past prevention and intervention efforts to impact on relevant risk factors and to address specific subgroup needs" (p. 25). Even programs that promote skills to resist peer and other social pressures to initiate use may overlook the need to interrupt the developmental sequence that is determined by, and results from, the influence and interplay of a host of risk factors. This position has led to a final phase of AOD prevention programs.

Contemporary approaches incorporate intervention at the individual, family, and environmental levels, with concomitant awareness of the different goals and tasks involved in primary, secondary, and tertiary prevention. The Interpersonal Relations strategy devised by Eggert, Seyl, and Nicholas (1990) is an example of a program in which high-risk students benefit from teacher modeling and structured peer group support to increase bonding to prosocial peer groups; strengthen commitment to the school and conventional norms of success; and reinforce AOD abstinence while teaching and remediating academic and social skills. Vorrath and Brendtro (1985) describe an approach for high-risk students that fosters bonding to a peer group whose purpose is to teach and practice problem-solving and coping skills.

The School Psychologist's Contributions

Apart from familiarity with the specialized AOD prevention knowledge base just outlined, school psychologists possess many of the skills required for program design and implementation. Following is a description of some of the areas in which school psychologists can offer expertise.

Needs assessment. School psychologists offer expertise in the assessment of needs for AOD prevention programs. A combination of methods, including surveys and interviews, can be used to learn the extent of the AOD problem in a school system and to develop specific target areas for prevention activities. Secondary benefits of needs assessment include the promotion of a common understanding of the problem; refutation of denial by community members, parents, and educators; and the establishment of a baseline for comparison following the implementation of programs.

Student surveys of AOD use should assess attitudes, perceptions, and risk factors in addition to information about AOD-use patterns and prevalence. Focus groups are recommended as an inexpensive and motivating format for collecting data from students and parents. Key informant surveys, or structured interviews with school and community experts, can provide information about resources and services.

Existing data can be gathered from school records (discipline referrals, expulsions and suspensions, attendance) and community agencies (law enforcement and treatment providers). Data available from community agencies include juvenile alcohol and drug arrests, juvenile drunk driving arrests, deaths caused by drugs or alcohol, hospital emergency room overdose admissions, and juvenile admissions to drug or alcohol treatment programs.

The results of a needs assessment are used to develop problem statements, citing prevalence data, student attitudes, and the prevalence and impact of identified risk factors. School psychologists can serve as a resource in this process by assisting with assessment design, data collection, and compilation and analysis of assessment results.

Comprehensive program planning. School psychologists can serve as key members of teams collecting data and analyzing assessment results, offering expertise in the development of long- and short-term goals, objectives, activities to meet objectives, and resources (personnel, time, space, equipment, and materials). In planning programs, each of the four methods described earlier should be considered (policy, education, alternatives, ad intervention/treatment/support) for each of three audiences in the school population (primary, secondary, and tertiary prevention).

Curriculum design. School psychologists can assist in curriculum selection, implementation, and evaluation by focusing attention on the need for developmentally sequenced programs which offer flexibility and adaptability to different teaching and learning styles, and by assisting in evaluating the success of curricula in meeting instructional goals.

Collaboration. Models for AOD prevention planning cite a team approach as the most effective and desirable vehicle for program design and implementation. Teams of parents, community representatives, educators, and students have been effective in designing prevention programs. Team models are also employed in the delivery of services by school personnel. School psychologists can serve as important team members, contributing expertise in team building, goal setting, intervention planning, interpersonal communication skills, problem-solving techniques, group process, and facilitating cooperation with team efforts by members of the school community.

Training. An effective AOD-prevention program requires training of school personnel, parents, and students themselves. School administrators, faculty, and staff require training to help them understand and identify risk factors, apply concepts of "protection" at every level of prevention, and intervene on problems in an effective manner. Parents require training in skills to enhance family management and develop effective support networks. Students involved in positive peer programs and student leadership groups require training in team-building and strategies to promote positive peer influence. School psychologists can serve as trainers, facilitators of skill and support groups, and links to training resources in the community.

Early identification. School psychologists bring a wealth of skill to the task of identifying students who are at risk for AOD involvement before the impact of risk factors becomes debilitating. Patterns of early school failure, rebelliousness, lack of commitment to school, deficits in interpersonal skills, behavior problems, and association with deviant peer groups can be identified as precursors to AOD involvement.

Intervention. Strategies for intervening on the circumstances or behavior of high-risk students address a range of personal and environmental factors. Traditional AOD intervention programs focused on tertiary prevention, in which efforts were made to interrupt the development of harmful patterns of use. With growing understanding of the role of risk and protective factors, intervention efforts are now directed toward the amelioration of conditions creating *vulnerability* to AOD use, including academic failure, peer rejection, and poor coping skills. Intervention seeks to inhibit, reduce, or buffer the effects of risk factors by promoting skill development and creating an environment in which students can embrace normative values and behaviors such as school achievement, personal and social competence, and identification with positive role models and peer groups. School psychologists offer expertise in devising, implementing, and evaluating the impact of interventions.

Evaluation. The value of school-based AOD-prevention programs can be demonstrated through ongoing evaluation activities. Summative evaluation, which describes program activities, participation levels, and the expenditure of resources, provides an overview of the prevention program itself. Impact or outcome evaluation, on the other hand, is oriented toward the measurement of the effectiveness of activities in meeting program goals.

School psychologists can participate in both forms of evaluation by helping to identify indicators of program *scope*, including number of student participants in programs, background characteristics of participants, activities included in the program, frequency and duration of activities, number of school staff and community members involved in programs, and resources allocated to programs. Indicators of program *impact* include data reflecting student knowledge and attitudes about AOD use; prevalence of use; feedback from students, teachers, and parents on program effects; student attitudes toward school and learning; student achievement; school climate; attendance; and disciplinary referrals related to AOD use.

Evaluation data can be collected through questionnaires and interviews, observations, and review of documents such as attendance and disciplinary records. With extensive training in data collection and measurement of behavior change, school psychologists should play a key role in evaluating the scope and effectiveness of AOD-prevention programs.

BEST PRACTICES

Recommended Program Components: Methods X Audiences

Comprehensive AOD-prevention programs consist of the following components:

- A system in which student behavior is monitored on a continuous basis by every member of the school staff, and which provides for prompt and effective action when student performance, characteristics, or circumstances (risk factors) signal the need for intervention.
- A coordinated plan for providing services to troubled and at-risk students, utilizing resources available in the school itself or in the community. Services are not limited to students known to be troubled by alcohol or other drug-related problems; rather, a "broad brush" program, addressing a range of problems and risk factors, is recommended.
- School curricula, activities, and climate which clearly and consistently support and convey a "no-

TABLE 1

Comprehensive School-Based Prevention Programs

	METHODS			
AUDIENCES	***Policy***	***Education***	***Alternatives***	***Intervention, Treatment/Support***
Primary Prevention	• Rationale for deterrence - Sanctions against AOD use - Reduced AOD availability	• Awareness of consequences of AOD use • Skills to resist negative influence • Effective coping skills	• Foster protective factors - Bonding to school - Positive peer affiliations - Accurate perceptions of AOD use	• Continuous monitoring of behavior and school performance • Abstinence support groups • Parents: Family management skills
Secondary Prevention	• Rationale for risk focus - Early identification procedures - Risk intervention procedures	• Intensive focus - Resistance skills - Coping with stressors • Arrest school failure trend	• Strengthen protective factors - Relationships with caring adults - Opportunities for responsible behavior - Positive peer affiliations - Foster school success	• Early identification activities • Academic, behavioral, and social remediation • Issue focused groups • Concerned persons groups • Parents: Problem-solving, limit-setting, and communication skills
Tertiary Prevention	• Rationale for recovery focus - Interruption of AOD use patterns - Recovery support - Abstinence enforcement	• Skills to achieve and maintain abstinence • Skills for coping with personal distress	• Serve "reclaiming" function - Establish/restore positive peer and adult affiliations - Provide AOD-free activities	• Interventions and referral for services • Insight groups • Abstinence (recovery support groups) • Parents: Linkage with community resources and support networks

use" message and provide students with opportunities, experiences, and skills that afford protection against AOD involvement.

These components are reflected in the methods of policy, education, alternatives, and intervention/treatment/support, with varying emphases and content for the three prevention audiences in school populations (see Table 1).

Policy. The AOD Policy adopted by a school system should reflect goals developed on the basis of a preliminary needs assessment. It is recommended that policies reflect a broad emphasis on AOD prevention, coupled with specific regulations and procedures that clearly indicate that AOD use or sales (by students and school personnel) will not be tolerated. Policy should be preceded by a statement of philosophy which clearly conveys the school system's beliefs and values regarding the nature of AOD problems; the emphasis on prevention, risk, early intervention, and protection in the school's comprehensive AOD program; and the role of the school in helping students to resolve problems associated with AOD use.

School policy is most effective when it is developed, promoted, publicized, and enforced in community-based efforts that include students, parents, law enforcement officials, and community representatives. Sanctions against AOD use have been cited as an environmental factor offering protection against initial AOD use. School policy provides a vehicle for expressing and enforcing such sanctions. Similarly, the availability of illicit substances, cited as a risk factor for AOD use, can be addressed through communication and cooperation with community law enforcement agencies and businesses offering alcohol and drug paraphernalia for sale.

As a guide for action in helping students to resolve problems associated with AOD use, policy should address the following issues:

- Specification of what constitutes an AOD offense by defining illegal substances or paraphernalia, the area of the school's jurisdiction (including school property and surroundings as well as school-related events), and types of offense (possession, use, and sale).
- Procedures to be followed for first-time offenders and repeat offenders and sellers. Consequences for policy violation should be stated clearly, with punitive action linked to referral for corrective ser-

vices. Procedures often include provisions for holding penalties in abeyance if students and parents agree to participate in corrective activities such as assessment or treatment.

- Circumstances under which incidents should be reported and a description of responsibilities and procedures for investigating and reporting incidents, with provisions for notifying parents and law enforcement officials.

Administrative regulations or enforcement procedures should be included or referenced in school AOD policies. These procedures describe the specific actions taken by schools to interrupt harmful patterns of behavior in ways that are likely to result in positive change.

For the *primary prevention* audience, policy serves as a deterrent to AOD use. For the *secondary prevention* audience, policy provides a rationale for early identification and intervention on risk factors. For the *tertiary prevention* audience, policy offers goals and procedures for interrupting use, supporting recovery, and enforcing abstinence. At every level of prevention, policy provides a clear statement of the school's commitment to foster protective factors through education, alternatives, and intervention/treatment/support methods.

Education. The role of education in a comprehensive AOD prevention program reflects a dual emphasis on reducing the prevalence and impact of risk factors while promoting and strengthening factors associated with protection from risk.

The United States Department of Education (1988) recommends that AOD prevention curricula reflect the following themes at all grade levels, K through 12:

- A clear and concise message that the use of alcohol, tobacco, and other illicit drugs is unhealthy ad harmful.
- Knowledge of all types of drugs, including what medicines are, why they are used, and who should (or should not) administer them.
- The social consequences of substance abuse.
- Respect for the laws and values of society.
- Promotion of healthy, safe, and responsible attitudes and behavior by correcting mistaken beliefs and assumptions, disarming the sense of personal invulnerability, and building resistance to influences which encourage substance abuse.
- Strategies to involve parents, family members, and the community in the effort to prevent use of illicit substances.
- Appropriate information on intervention and referral services, plus similar information on contacting responsible adults when help is needed in emergencies.
- Sensitivity to the specific needs of the local school and community in terms of cultural appropriateness and local substance abuse problems (p. 10).

Decisions about whether to purchase, adapt, or develop prevention curricula are based on several considerations, including state requirements. Most states require AOD prevention education, while some provide minimum curriculum standards and certification requirements for teachers. A number of states have adopted or designed their own AOD prevention curricula. The costs associated with "packaged" curricula, including materials and training, can be prohibitive. A recent and popular trend finds school systems working with law enforcement agencies to develop and implement aspects of the prevention curriculum.

Consistent with research findings on the effectiveness of educational programs and curricula, schools should develop or adopt programs that emphasize training in skills to resist negative peer, adult, media, and community influence, while promoting the development of adaptive general coping skills and social competence.

Education directed toward a *primary prevention* student audience should increase students' awareness of the influence of peers, media, and the culture in promoting AOD use and teach specific skills for resisting and coping with these negative influences. Instead of providing technical information about AOD use and its effects, education should counteract perceptions among youth that AOD use is commonplace, thereby weakening perceived social support for such use. Information about the consequences of AOD use should emphasize immediate, short-term effects on matters of interest to students (such as interpersonal relationships), rather than focus primarily on long-term adverse health consequences.

An example of a skill-focused curriculum suited to elementary and middle-school students can be found in materials developed by Sharon Scott (1985; 1988; 1992), which train students (beginning at age 5) to recognize and deal effectively with problem situations through assertiveness and refusal skills. Elias (1993) offers a comprehensive resource describing programs and activities to promote social decision making and life-skills development for students at the middle-school level. A similar resource (Elias & Clabby, 1989) is available for educators who work with children at the elementary level. The Life Skills Training curriculum (Botvin, 1989; 1990) is recommended as a comprehensive program for adolescents.

The *secondary prevention* student audience requires, in addition, specific skill-training and remedial activities designed to reduce or buffer the impact of identified risk factors. Because school failure is a key component of the developmental sequence that often leads to AOD problems, interventions aimed at correcting deficiencies and building a sense of academic competence should receive special attention. Disengagement from the mainstream, leading to exposure to unconventional behaviors such as AOD use and association with like-minded peers, is often an unforeseen consequence of pull-out remedial programs. Therefore, efforts should be made to draw at-risk students into the educational mainstream, where positive peer associations and commitment to normative standards are more likely to occur.

Cooperative learning strategies, described in an earlier edition of *Best Practices in School Psychology* (Peterson & Miller, 1990), hold special promise for students in the secondary prevention audience because of their potential for improving learning and fostering more prosocial associations between high-risk and low-risk peers.

The *tertiary prevention* student audience, those who have already engaged in AOD use, benefit from the educational strategies outlined for the secondary prevention audience. In addition, however, they require specialized assistance to enable them to abandon destructive patterns of use; replace identification with deviant, socially-rejected groups with positive peer group affiliation; and learn more effective personal coping techniques. These educational objectives are often accomplished in programs offered in schools under the method of intervention, treatment, and support.

Effective prevention programs address the educational needs of school personnel and parents, in addition to those of students. Education enables school personnel to understand the role of risk and protective factors in the development of AOD problems and to learn strategies for combating risk and fostering protection. Parents can be taught skills for effective and consistent family management, including methods for setting and enforcing rules regarding AOD use.

Alternatives. As a result of its expansion beyond a more traditional focus on AOD-free activities for youth, the method of alternatives provides students multiple opportunities for meaningful and responsible participation in school. The emphasis of this approach is on the promotion of factors that are protective in nature, including prosocial bonding with peers and the school; student involvement in activities in which they can assume responsibility and achieve success; and formation of caring, nurturing relationships between school staff and students. Unlike educational programs focusing primarily on information dissemination and skill development, the method of alternatives is uniquely effective in addressing motivational issues and enlisting student commitment to the goals of school-based prevention programs.

In many schools, participation in alternatives is reserved for students who have demonstrated a capacity for responsible behavior. As a result, programs often address only the needs of the primary prevention audience, with the secondary and tertiary prevention audiences relegated to the role of recipient or beneficiary of service. This practice overlooks the power of alternatives for at-risk and troubled students, for whom participation offers an opportunity to achieve success while establishing bonds with positive peer groups and caring adults.

A key consideration in developing alternatives, then, is the recruitment and engagement of students from all three audiences. For students in the *primary prevention* audience, alternatives afford opportunities to expand and strengthen existing skills and prosocial motivation. Students in the *secondary prevention* audience are encouraged to participate in alternatives in order to establish and strengthen motives and skills to protect against and buffer the influence of risk factors. For the *tertiary prevention* audience, alternatives serve a "reclaiming" function, breaking patterns of failure, disengagement from school, and identification with deviant peer groups.

Classroom meetings, peer mediation programs, and service on student-faculty committees provide opportunities for students to assume responsibility for decision making and problem solving. Peer assistance programs such as peer tutoring, peer counseling, peer facilitation, buddy systems, peer-led workshops, and cross-age teaching provide regular opportunities for students to make meaningful contributions to others while improving their own academic and social skills. The variety of peer helping programs is limited only by the creativity of students and school staff. Mentoring programs, in which students are assigned to trained adult staff, foster trust and stability in student relationships with caring adults.

Intervention, treatment, and support. The focus of intervention, treatment, and support activities differs for each of the three prevention audiences. The primary prevention audience, exhibiting no characteristics associated with increased risk for AOD use, generally receives less attention under this category of methods. Recognizing, however, that developmental events (such as transitions from middle to secondary school) and environmental circumstances create risk, schools address the needs of the *primary prevention* audience through strategies designed to make alcohol and other drugs less available; to create networks of informed parents, community members, and school personnel that discourage use through monitoring of youth activities; to support abstinence among students; and to create a school climate in which behavior and achievement problems are identified for early intervention purposes.

Student Assistance Programs provide a vehicle for identifying and addressing the needs of the *secondary* and *tertiary prevention* audiences. Many schools have abandoned the more traditional focus on AOD use as a criterion for referral to Student Assistance Programs in favor of referral for any problem having an adverse impact on school performance. This "broad brush" approach is recommended as a means for providing more effective early intervention to a wider range of at-risk and troubled students.

Muldoon and Crowley (1989) describe a model for Student Assistance Programs which includes six steps:

- *Identification*, which requires the recognition of cues and signs of personal, behavioral, social, or academic problems.
- *Initial Action*, which includes discussion with troubled students and referral for Student Assistance Services.
- *Pre-Assessment*, in which school performance data is gathered and analyzed to arrive at an initial determination of needs.
- *Referral to Needed Services*, whether school- or community-based.
- *Provision of Appropriate Care*, in which schools provide direct service or assist students in accessing community services.
- *Support for Change*, in which schools help students maintain new and healthy patterns of behavior.

Among the services most commonly offered in Student Assistance Programs are

- *Insight Classes*, which consist of a highly structured series of presentations, assignments, and discussions for students who have encountered problems with AOD use.
- *Abstinence Support Groups*, which support AOD-free lifestyles for abstainers and those who have been treated for AOD addiction.
- *Concerned Persons Groups*, which provide support and skill-training for students affected by the use of family members and friends.
- *Issue-Focused Groups*, which foster coping skills and emotional support for students whose characteristics or circumstances place them at risk for AOD problems.

To enlist support for the goals of the Student Assistance Program as a trustworthy and effective resource for at-risk and troubled students, information about the program should be made available in the form of written materials and presentations to student, faculty/staff, and parent groups.

School personnel require instruction in strategies for identifying, confronting, and correcting behavior problems in students. In addition, they should receive clear information about their role as referral agents and facilitators of change for students involved in the Student Assistance Program.

Despite the fact that insufficient evidence has been gathered to demonstrate their effectiveness (Schinke, Botvin, & Orlandi, 1991), programs that foster parent involvement represent a promising vehicle for prevention. Programs that extend the role of parents beyond that of participant and supporter to one of teaching and leadership are growing in popularity. Parent-to-Parent, developed by the Parents Resource Institute for Drug Education (PRIDE; Oliver, Creagh, & Fonesca, 1988) is a peer-driven program providing parents with information about AOD use, barriers to change, and skills for preventing and intervening on AOD use among children and youth. A model for parent support based on a plan for attracting and organizing parents into prevention networks based on children's grade levels is offered by Houghton (1986). Talking With Your Kids About Alcohol (Daugherty & O'Brien, 1987), a parent training program based on a lifestyle risk-reduction model, encourages parents to provide children with information about risks associated with AOD use and teaches specific communication techniques for conveying parental expectations and setting limits and consequences for use.

Program Recommendations: Legal Considerations

This section offers general recommendations for school-based prevention programs based on a review of relevant laws, policies, and judicial precedents. A more comprehensive review of legal issues is available in material recommended in the Annotated Bibliography accompanying this chapter. School officials should consult with legal counsel to determine the application of legal principles in their schools and to ensure compliance with all legal requirements.

- *Develop, publish, and follow a written policy.* Adherence to written policy affords substantial protection to schools when claims of discrimination and failure to safeguard other student rights arise. The policy should address, at minimum, the school's position regarding the use, possession, and sale of alcohol and other drugs, and outline the steps that will be taken in the event of a policy violation. State and local laws usually determine the range of sanctions that is permissible. The use of suspension and expulsion are subject to federal and state due process safeguards, including notice and an opportunity to be heard.
- *Inform students of limits on confidentiality.* Initial interview sessions with students who have been referred for AOD-related services should include a candid discussion of issues related to confidentiality, particularly at the high school level. As a general guideline, it is advisable to inform students that, while the confidentiality of shared in-

formation will be protected, there are circumstances when such information must be shared. These circumstances vary depending on state law, but generally include situations where there is a suspicion of abuse and neglect; when there is danger to the student or others; and when there is reason to believe that a crime has been committed.

- *Review record-keeping procedures.* Conventional wisdom applies to AOD programs as it does to other school programs and activities:

  If you practice it, write it down;
  If you said it, write it down;
  When you act, write it down.

  Actions are more easily defended when they arise from the provisions of written policies and procedures. Written documentation of statements or actions should include the date, time, location, nature of the incident, parties involved, and a description of the statements made or actions taken.

- *Monitor program-related communication within the school.* Disclosure of information about students to parties outside the school is subject to a variety of legal constraints beyond the scope of this chapter. With respect to within-school communication, however, several guidelines apply. Only program personnel and administrators directly responsible for the AOD prevention program may share information about students who have applied for or received AOD-related services. However, acknowledgment of referral and general information about the student's progress may be shared with referring teachers and involved school personnel, as long as the information does not identify the student (directly or by implication) as an alcohol or drug abuser. When information is needed to provide appropriate medical care in an emergency situation, it is permissible — and, often, advisable — to share information with a nurse or physician.

- *Notify parents and, when required, obtain consent for services.* School policies should describe the types of services for which parental notification and consent are required. As a general rule, consent should be obtained if the AOD prevention program is not directly related to academic instruction and is not a part of the school's required curriculum. A support or skill-development group, for example, to which students are referred and in which they are expected to share information about attitudes, traits, opinions, beliefs, or feelings, should have provisions for obtaining parental consent. Although formal consent is not required for programs which are part of the curriculum, parental notification provides an opportunity for parents to inquire about the program and to object to their child's participation.

- *Provide adequate training to program personnel.* Schools should always ensure that program personnel have experience and are competent to provide the specific type of service offered. For example, facilitators of support groups should have training in group techniques. Teachers and other staff who make referral should be trained to recognize signs of AOD involvement, and should understand the school's policy and procedures for referral.

- *Develop a plan for searches.* School policy should provide explicit guidelines for searches of students as well as their possessions and lockers. A landmark United States Supreme Court ruling (*New Jersey v. TLO*) provides that:

  > Those responsible for the search must clearly state which school rule or law was violated;
  >
  > The information on which the search is based must be recent, credible, and link the student to the violation;
  >
  > The scope of the search must be reasonable and in context, given the student's age, sex, and the nature of the infraction;
  >
  > The search must be based on a reasonable suspicion that the student has violated rules or law.

Similarly, drug testing should be employed only when there is reasonable suspicion of drug use by a student, and not as a "blanket" procedure for groups of students.

- *Develop a plan for referral to outside agencies.* Because school personnel are not qualified to provide comprehensive care for AOD problems, schools have frequent occasion to make referrals to outside agencies. It is advisable to channel referrals through a designated party in the school (often the school counselor or school psychologist who may, depending on state law, have additional legal protection not available to teachers and other staff). Although students may be entitled to obtain outside services without parental notification, it is advisable to encourage students to discuss their situation with, and seek the advice of, their parents or guardians. When making a referral, school personnel should take care not to impose their views or advocate any particular agency outside the school. School officials should request authorization to release confidential information to agency personnel.

SUMMARY

Several factors support the feasibility of school psychologists' involvement in school-based alcohol and other drug (AOD) prevention programs. School psychologists possess training and expertise in the areas of needs assessment, program planning, curriculum design, collaboration, training, early identification, intervention, and program evaluation. Their familiarity with the structure and organization of schools serves as an asset in planning and enlisting support for programs. Myers (1989) notes that prevention approaches "will be most successful if they are viewed by teachers as consistent with the educational process, and if they can be implemented with minimal added expenses and intrusiveness" (p. 393). Because school psychologists are familiar with the ongoing structures, organizations, and routines of school functioning, they play a dual role of "inside expert" and "outside consultant," bringing knowledge of research on the role of AOD risk and protective factors and components of effective programs.

Prevention programs are most effective when they involve multiple levels of influence, including peers, school personnel, and community resources (parents, community leaders, media) in efforts to reduce the onset, use, and abuse of alcohol and other drugs (Kazdin, 1993). Similarly, interventions are most likely to succeed when they avoid a narrow focus on the variable of AOD use, in favor of approaches that address multiple risk factors at both individual and environmental levels (Lorion & Ross, 1992). Experience indicates that effective programs extend their scope beyond information giving and skill training to include strategies for promoting protective school environments and enhancing prosocial motivation.

Research suggests that the phenomenon of substance abuse is the produce of a developmental pathway characterized by early failure in personal, social, and academic tasks, leading to associations with negative peer groups in which initial AOD use is likely to occur. When initial use is followed by relief from personal distress and acceptance of a deviant identity, youth become trapped in a lifestyle which rewards and escalates deviant and nonconforming behavior, including AOD use.

An understanding of the interaction between program methods and prevention audiences provides a framework for program planning and evaluation. A theme of intolerance of AOD use, coupled with a commitment to facilitate and support recovery from harmful and destructive patterns of behavior, should be clearly and consistently expressed in every aspect of school programs. The purposes and content of policy, education, alternatives, and intervention/treatment/support activities should be tailored to the needs of students in the primary, secondary, and tertiary prevention audiences.

The purpose of school-based programs for the *primary prevention* audience is to foster the attainment of characteristics which afford protection against AOD use. Educational efforts should focus on the development of awareness of the negative short-term consequences of AOD use and the establishment of effective coping skills, including techniques for resisting negative influence. School programs should focus on enhancement of student performance and bonding to school, formation of positive peer associations, promotion of accurate perceptions of AOD use, and policies providing sanctions against AOD use. Schools should work with parents to provide assistance in developing more effective family management skills and with community members to reduce the availability of alcohol and other drugs.

The *secondary prevention* audience is served through school programs which seek to reduce or buffer the impact of risk factors. Educational interventions should provide a more intensive focus on the development of coping and resistance skills, coupled with efforts to arrest emerging trends of school failure. School programs should foster caring relationships between students and adults and implement strategies which place school success and positive peer affiliation within reach of troubled and at-risk youth. Responses to behavior problems should extend beyond the provision of sanctions to the creation of opportunities for responsible and rewarding behavior. Interventions with families should be extended to include training in problem-solving and communication skills, enabling parents to set and enforce limits for behavior.

The purpose of school programs for the *tertiary prevention* audience is to interrupt and eliminate patterns of AOD use. In addition to the interventions recommended for the secondary prevention audience, educational programs for the tertiary prevention audience should provide opportunities for students to learn and practice specific skills for achieving and maintaining abstinence and for coping with personal distress. School programs also serve a "reclaiming" function for this audience by drawing them into the mainstream, thereby providing opportunities to establish or restore positive peer and adult affiliations and commitment to normative standards of behavior. Interventions with families may require linkages with community-based resources and support networks of concerned parents. Efforts to reduce AOD availability and disrupt use patterns are most successful when they involve communication with law enforcement agencies. For the tertiary prevention audience, the provision of AOD-free activities is of special importance, and efforts should be made to engage students' interest and commitment to such programs.

In a 1992 article entitled *America 2000 and the National Education Goals Panel: Contributions of School Psychology*, George Batsche, former president of the National Association of School Psychologists, described the role school psychologists can play in accomplishing the goal that *every school in America will be free of drugs and violence and will offer a disciplined environment conducive to learning*. Participation in school-based AOD prevention programs is encouraged as a means for school psychologists to assume meaningful leadership in efforts to combat a problem that is recognized as a significant threat to the welfare and future of the nation's youth.

ANNOTATED BIBLIOGRAPHY

Anderson, G. (1988). *When chemicals come to school: The student assistance program model.* Greenfield, WI: Community Resource Press (P.O. Box 20979, Greenfield, WI 53220).
This book is a comprehensive and widely acclaimed resource for school-based AOD programs. A "must" for the professional library of educators responsible for program design and implementation, it provides detailed descriptions of components of Student Assistance Programs, including policy design, the role of school personnel and parents, team development, intervention and referral models, and student support group curricula.

League, V., & Pump, S. (1988). *A policy development manual for drug-free schools.* Oakland, CA: Vincente & Associates (2101 Webster Street, Suite 1700, Oakland, CA 94612).
This book serves as an invaluable source of step-by-step guidance through the process of school policy development. It includes a useful and comprehensive summary of legal issues pertinent to school-based programs as well as sample policies adopted by representative school systems.

Schinke, S., Botvin, G., & Orlandi, M. (1991). *Substance abuse in children and adolescents: Evaluation and intervention.* Newbury Park, CA: Sage Publications (2455 Teller Road, Newbury Park CA 91320).
This publication of Volume 22 of the journal *Developmental Clinical Psychology and Psychiatry* offers a comprehensive review of research on the effectiveness of various prevention programs, including information dissemination, affective education, and skill-training approaches. Intended for professional audiences, it also reviews formats for adolescent treatment programs and offers an excellent discussion of evaluation methods for prevention and intervention activities.

United States Department of Education. (1989). *What works: Schools without drugs.* Available from the National Clearinghouse for Alcohol and Drug Information (P.O. Box 2345, Rockville, MD 20852).
This booklet, available free of charge from NCADI, provides an overview of the AOD problem; offers action plans for parents, schools, students, and communities; describes specific drugs and their effects; provides general information about legal issues; and offers information about resources for prevention-related products and services.

Western Center for Drug-Free Schools and Communities. (1988). *Planning for drug-free schools and communities: Participant manual.* Portland, OR: Northwest Regional Educational Laboratory (101 S.W. Main Street, Suite 500, Portland, OR 97204).
This manual, consisting of materials employed in a 2-day training workshop for school personnel, offers extensive information and guidelines for promoting awareness of AOD problems and planning appropriate prevention efforts. It describes school team models, needs assessment methods, planning activities, policy issues, prevention curricula, evaluation procedures, and suggestions for working with parents and community members.

Best Practices in Addressing HIV/AIDS Issues in the School

Katrine Haefli
John B. Pryor
Steven Landau
Illinois State University

> Herbert Johns, superintendent of a medium-sized suburban school district, looked across his desk at the parents of Michael Tobin. They were young, relatively affluent, active in the Parent/Teacher Association — and their only child had AIDS . . . Not a soul, other than the three people in the room, knew. The Tobins wanted to keep it that way. They wanted Michael to enter second grade like any other child. "It will all end for him soon enough; just let him have a few months of normal life," they pleaded.
>
> Johns scanned the youngster's school records again. A model first-grader, well-behaved, bright, verbal — what a tragedy! None of the three adults doubted that Michael's life would become a living hell once the story was out . . . : protests by parents, loss of friends, legal battles, media attention. What a way for a child to die, Johns thought to himself — isolated, feared, and guilt-ridden.
>
> The adults decided to keep Michael's [medical] results confidential; only the president of the school board would be let in on the secret. And so, in early September, Michael entered second grade.
>
> Shortly thereafter, it happened. During recess one afternoon, three boys fell from the monkey bars. It was not a big accident — just scraped hands and knees and a lot of blood. With only two antiseptic wipes for three little boys — one of them, Michael — an unknowing teacher used the same wipe on six bloody knees and six upturned hands.
>
> Conscience-stricken and in a panic, Michael's parents told the school nurse about his condition when the nurse phoned them to report what she perceived to be an ordinary playground mishap. No one could have imagined the chaos that ensued. Michael's school was closed. Classrooms were washed down, and the restrooms were scrubbed by workers wearing gloves and face masks. Teachers and students refused to enter the building. Then came the lawsuits: three separate tort liability cases and two class-action suits citing prior knowledge, breach of duty, negligent standard of care, and proximate cause. (Keough & Seaton, 1988, p. 58)

This situation, although fictitious, is based on real cases. It highlights the possibility of having an unidentified HIV-carrier in the school — whether it be a student or staff member — and an uninformed, unplanned reaction to a crisis.

The purpose of this chapter is to provide school psychologists with information regarding HIV/AIDS as it pertains to children in the schools. Currently, there are few known HIV-infected children in the schools. However, with increasing prevalence of HIV among adults, youth, and infants, and with advances in medicine that prolong the lives of those with AIDS, there will be increasing numbers of students who either are infected with HIV or who have a family member infected with HIV. School psychologists, then, need to be aware of the current epidemiology of HIV/AIDS among youth and the legal and policy issues concerning the school attendance of HIV-infected children. School psychologists must also be prepared to address potential problems in mainstreaming the HIV-infected child and in providing appropriate consultative services to facilitate this process. Educating the community, students, and school personnel about HIV/AIDS is the key component in effectively addressing HIV-related issues in the schools. Therefore, school psychologists should take a proactive role in planning and implementing AIDS education and HIV-related services in the schools. In this way, students directly and indirectly affected by the HIV epidemic can be provided optimal educational and psychosocial services in the schools.

In the following overview, AIDS and HIV infection are described, and the prevalence of the disease is discussed. Under *Basic Considerations,* the legal and policy issues regarding children with HIV infection and the task of mainstreaming these children in the schools are presented. In addition, the necessary precautions that all school personnel and students should practice are provided, along with the accompanying AIDS education that is crucial in successfully dealing with the AIDS epidemic in the schools. Finally, best practices for school psychologists dealing with HIV in the schools are presented.

OVERVIEW OF HIV/AIDS

HIV infection refers to infection with human immunodeficiency virus, regardless of the presence of overt illness or clinical manifestations. *HIV-related disease* refers to the presence of HIV infection and the presence of clinical manifestations which may or may not be life threatening. *Acquired immunodeficiency syndrome* (AIDS) represents essentially the later stages of HIV disease. The HIV virus attacks and ultimately compromises a person's immune system. Persons with AIDS are subject to a variety of opportunistic diseases which rarely infect people with healthy immune systems. The onslaught of such opportunistic illnesses in a weakened immune system eventually results in death for the person with AIDS (Weiss, 1993). Clinical diagnosis of AIDS hinges in part upon the presence of these opportunistic infections. The National Centers for Disease Control and Prevention (CDC, 1993b) has revised its definition of AIDS three times: in 1985, 1987, and in 1992. The revisions have broadened the range of AIDS-indicator diseases and conditions, and have used HIV diagnostic tests to improve the sensitivity and specificity of the definition.

Transmission of HIV

There are three major ways in which HIV is transmitted: (a) perinatally from an infected mother, (b) from exposure to infected blood or blood products, and (c) from unprotected sex with an infected person. Although all babies born of HIV-infected mothers carry maternal antibodies to HIV, only about one third are actually infected with the virus. Reliable diagnosis is generally possible after about 15 months (Chambers & Lindenbaum, 1993). The primary means by which people are infected with contaminated blood is through intravenous drug use. Needle sharing is a common practice among many intravenous (IV) drug users. This practice permits the passage of the virus from one user to the next. Exposure to contaminated blood is also possible through transfusions, the use of clotting agents in treating hemophilia, and accidental needle pricks encountered by medical personnel. Systematic screening of the blood supply in the United States has greatly reduced the number of infections related to transfusions and the use of clotting agents. The institution of universal precautions has significantly reduced the risk of medical personnel. The primary means of transmission is still unprotected sex with an infected person. The HIV virus may be present in either the semen or vaginal secretions of an infected person. Sexual activity in which a partner comes in contact with either of these fluids runs a risk for HIV transmission. CDC (1993a) reports that 56% to 69% of adult/adolescent AIDS cases in the U.S. involved a sexual contact risk factor. Among adolescent boys with AIDS 33% to 41% involved this risk factor. Among adolescent girls, 50% involved a sexual contact risk factor.

HIV is not spread by casual contact. In studies of hundreds of households where family members have lived with and cared for AIDS patients (sometimes in circumstances where it was not known that the person was infected with HIV), there has never been a case of transmission through casual contact (CDC, 1993a). If HIV is not transmitted in circumstances where kitchen and bathroom facilities, meals, eating and drinking utensils, and even toothbrushes are shared repeatedly for prolonged periods of time, it seems even less likely that HIV could be casually transmitted in other social situations such as schools or offices. It also should be noted that studies in Africa and Florida have found no evidence for household HIV transmission in mosquito infested areas. So, there seems no danger of HIV transmission through insect bites.

Consequences of HIV Infection

In addition to its effects upon the immune system, HIV has been found to affect the nervous system directly (Fletcher et al., 1991; Navia, Cho, Petito, & Price, 1986). The dementia aspect of AIDS (e.g., brain atrophy, encephalopathy) is believed to be separate from the immunodeficiency aspects and may be caused by direct infection of the brain with HIV. It is estimated that between 30% and 60% of adults with AIDS evidence neurological complications, whereas 50% to 90% of children evidence such complications (Byers, 1989). Indicators of neurological involvement in adults include general mental slowness, impaired concentration, mild memory loss, and motor skills impairment (e.g., progressive loss of balance, leg weakness). Younger children, particularly those infected perinatally, seem especially susceptible to neurological damage from HIV infection (Epstein, Sharer, & Goudsmit, 1988). Neurological damage is one of the most common causes of death in pediatric AIDS cases (Plesser, Foster, & Siegel, 1987). The HIV virus appears to have a profound effect upon brain development in pediatric cases and subsequently upon the attainment of motor, intellectual, and developmental milestones (Byers, 1989). In some cases, young children with AIDS have been found to regress and lose milestones previously attained. Recent research indicates that treatment with AZT (Aziodothymidine) may alleviate some of the AIDS dementia effects found in children (Culliton, 1989).

Epidemiology of HIV/AIDS

In early 1993, CDC reported a cumulative total of 5,647 cases of AIDS in persons under the age of 20 in the U.S. Almost 64% of these were children under the age of 5. The vast majority of the children under 5 were infected perinatally by their mothers. Moving from childhood to adolescence, one finds a different characteristic pattern of infection. For example, for adolescents ages 13–19, 48% of the males and 73% of the females were infected either via intravenous drug use or sexual contact. Minority children and adolescents have been hardest hit in this epidemic. Almost three-fourths of the AIDS cases in persons under 20 have been among Black and Hispanic youth.

While the number of children and adolescents with AIDS represents less than 2% of the total number of known AIDS cases in the U.S., AIDS and other manifestations of HIV infection represent a growing problem for schools for at least four reasons. First, while the development of a vaccine for HIV seems on the distant horizon, symptomatic treatment drugs have been and continue to be developed. These will result in an increasing number of children who will live to school age (Byers, 1989). Second, the rates of HIV infection continue to grow among children and adolescents in the U.S. (Hein, 1992), particularly in urban areas. Third, more adolescents are probably infected with HIV than current statistics reveal. For adults and adolescents, current estimates suggest a typical latency period of about 10–11 years from infection with the HIV virus to the development of AIDS (Gayle, Manoff, & Rogers, 1989). This suggests that the majority of adolescents with HIV infection is asymptomatic and would not be reflected in CDC counts of AIDS cases. Since 18% of the male and 24% of the female AIDS cases reported to CDC through March of 1993 involved people aged 20–29, one can infer that many of these people became infected while adolescents. Fourth, HIV disease affects families. Although uninfected themselves, school-age children with siblings, parents, or other family members who are infected with HIV bear the stigma and the personal strains of living with someone who has this terrible illness (Pryor & Reeder, 1993).

BASIC CONSIDERATIONS

Legal and Policy Issues

In 1985, the CDC and the National Educational Association issued guidelines concerning the attendance of HIV-infected children in the schools (Kirkland & Ginther, 1988). For most infected children, CDC recommends continued attendance in unrestricted school settings. More restricted environments are recommended for preschool aged children and neurologically handicapped children who lack control over body secretions and those who display behaviors such as biting and drooling. Section 504 of the Rehabilitation Act of 1973 and the Education for All Handicapped Children Act of 1975 (EHA) have provided the basis for legal arguments concerning HIV-infected children's rights to attend public schools. An important legal precedent for considering AIDS a handicap was set in the case of *Thomas v. Atascadero Unified School District* (1987). This case involved an HIV-infected child who was barred from kindergarten after he bit a classmate. The federal court ruled that the child's condition was a protected handicap and ordered that the child be readmitted to school. The court contended that the school had not shown that the child's presence in the classroom presented a significant risk for transmission.

The child in the *Thomas v. Atascadero Unified School District* case manifested some observable symptoms of AIDS. In other cases, the courts vacillated on whether simply being infected with HIV without any obvious symptoms also might be considered a handicap (for example, see *School Board of Nassau County, Florida v. Arline*, 1987). Fortunately, the Americans with Disabilities Act (ADA) of 1990 extended the definitions of disabilities offered in the Rehabilitation Act to explicitly cover both persons with symptomatic AIDS and asymptomatic carriers of HIV (Pyle, 1992). In the ADA, Congress recognized the power of the stigma associated with HIV/AIDS even when no obvious symptoms are present, and the importance of protecting persons with HIV/AIDS from discriminatory practices.

In addition to federal laws, the majority of states have developed policies concerning school attendance for HIV-infected children. Katisiyannis (1992) found that 41 of 46 states surveyed had school attendance policies for children with HIV. Eighty-three percent used CDC guidelines in developing their policies. However, only 39% mandated adherence to state policies by Local Education Agencies.

Some of the most complex issues faced by school officials in dealing with HIV-infected children concern confidentiality and the right of privacy. The CDC (1985) guidelines on school attendance for HIV-infected children warn of the potential problems of revealing a child's HIV status to his/her classmates. CDC urges school personnel and others involved in the care and education of these children to exercise sensitivity to the need for confidentiality and the right to privacy. Both the EHA and the Family Education Rights and Privacy Act contain prohibitions on unconsented disclosures of personally identifiable information about students (U.S. Department of Education, 1987). Under these acts, the disclosure of HIV status to appropriate school officials could be permitted, if justified by public health or other legitimate considerations. The states have developed their own laws and guidelines on these issues. Katisiyannis (1992) found that all of the states he surveyed had policies on disclosure of HIV status for school children. Despite the most sophisticated school policies, practical problems still exist for maintaining confidentiality. The most likely source of a breach of confidentiality is the child, parent, or guardian (Pyle, 1992). Once a person's HIV status is revealed, the potential exists for massive negative reactions from other children and parents (Pryor & Reeder, 1993). These include the social ostracism of the HIV-positive child and in some cases acts of violence against the child and his/her family. However, such reactions are avoidable if a proactive effort is made to educate children and their families about HIV/AIDS, and prepare them for dealing with the HIV-infected person in a realistic and humane manner (Schmitt & Schmitt, 1990).

Mainstreaming the Child with HIV/AIDS

In spite of media coverage of negative community reactions to mainstreaming children with HIV/AIDS in the schools, there has been a paucity of research on how parents and school personnel react to the prospects of an HIV-infected child in the classroom. However, given that children with AIDS will experience cognitive and developmental problems in the advanced stage of the illness and will, therefore, have frequent or prolonged absences from school, the research on disabled and chronically ill children may prove relevant to an understanding of what HIV-infected children may face in the schools.

Although advances in inclusion continue to be made, it has been known for some time that, in general, most regular education teachers still prefer special class placement for students with disabilities (O'Reilly & Duquette, 1988), educable mentally handicapped and behavior disordered students (Goupil & Brunet, 1984; Williams & Algozzine, 1979), and emotionally disturbed students (Shotel, Iano, & McGettigan, 1972). In addition, teachers report being uncomfortable with meeting the academic needs of chronically ill children (Johnson, Lubker, & Fowler, 1988).

There are various explanations for teachers' discomfort in teaching chronically ill or disabled students. First, teachers often perceive themselves as ill prepared to teach these students. This includes not having necessary information about a specific medical condition or not having the educational preparation to meet the needs of the student with a specific disability or chronic illness (Aksamit, 1990; Hannah & Pliner, 1983; Johnson et al., 1988). Second, teachers seem to worry about insufficient time to prepare individualized material for the student with disabilities and the student experiencing health-related absences (Morsink, Blackhurst, & Williams, 1979). Thus, the disabled or chronically ill student may be perceived as one who places an excessive demand on teacher time. Third, there is evidence that teachers are concerned about classroom management of disruptive behaviors presented by some disabled or chronically ill students (Aksamit, 1990; Johnson, Gold, & Vickers, 1982; Johnson et al., 1988). It seems probable that these same barriers to inclusion would also apply to the HIV-infected child. In addition, teachers have expressed concern for the safety of the health impaired child in the classroom (Johnson et al., 1988), which is clearly relevant to the child with AIDS who is more vulnerable to opportunistic infection.

There is limited research on teacher concerns about HIV-infected students, and few specific guidelines for appropriate educational services for these students. Few, if any, teacher training programs provide preservice teachers with information about the educational needs of HIV-infected students. In addition, limited information has been given to teachers about the HIV-infected student's potential to be injured or the probability of contracting opportunistic infections from other students. Most importantly, many misconceptions regarding the transmission of HIV are still prevalent. Students infected with HIV who are assaultive, bite other students, are incontinent, or who drool may elicit concern about HIV transmission to others. Transmission fears are also evident in the cafeteria (e.g., sharing of eating utensils) and on the playground (e.g., mosquito bites). Ballard, White, and Glascoff (1990) found that 30% of preservice elementary teachers would feel personally threatened by a student with AIDS in their class, 20% did not understand the basics of HIV transmission, and less than half knew how to protect themselves from infection.

Brucker, Martin, and Shreeve (1989) also found that many teachers do not think they should be required to teach HIV-infected students and do not agree that these students should be allowed to attend school. In addition, Peach and Reddick (1989) found that the majority of teachers and school administrators surveyed in rural Tennessee felt uncomfortable with their level of knowledge about AIDS, thought that students and school personnel are at risk for HIV infection when there is an HIV-infected person at school, and thought that school personnel or students with HIV should not be allowed to remain in school.

Reluctance towards mainstreaming an HIV-infected child may be further compounded by the fact that HIV and AIDS, even pediatric AIDS, evoke strong negative social connotations. From an epidemiological perspective, HIV was initially identified in the United States among the male homosexual community and IV drug users. Therefore, attitudes and beliefs regarding HIV may be the product of one's disposition towards these minority groups considered deviant by the majority. Thus, stigma, especially associated with sexual orientation, may be applied to any individual with HIV, regardless of how that individual contracted the virus (Pryor & Reeder, 1993).

If school psychologists examine the literature that describes how to facilitate mainstreaming of students with other disabilities and chronic illnesses, they may be better prepared to meet the mainstreaming needs of children with HIV/AIDS. Successful mainstreaming of the student with HIV will likely include a focus on positive attitudes toward persons with HIV/AIDS, adequate knowledge regarding AIDS and HIV transmission, appropriate psychoeducational interventions, and environmental engineering that offers support and resources to teachers and other school personnel servicing these students. Thus, successful mainstreaming of HIV-infected children requires a collaborative effort in which planning, training, and support are necessary.

AIDS Education

Education of students, school personnel, and the community about HIV/AIDS must precede any successful effort at mainstreaming the HIV-infected child in the school. School psychologists, along with teachers and other school personnel, play an integral role in ensuring the success of appropriate and comprehensive educational services to the student with HIV/AIDS. In addition, school psychologists' expanding consultative role places them at a significant advantage in disseminating accurate information to school personnel, as well as members of the community, and in dispelling myths regarding HIV/AIDS. It is therefore important for the school psychologist to take a proactive role in

- Sensitizing the school administrators, as well as the community, to the importance of AIDS education in the schools.
- Consulting on education programs for schools and the community which address both prevention of HIV infection and attitudes toward infected individuals.
- Designing and implementing a developmentally appropriate presentation of AIDS education at all grade levels.
- Ensuring that the medical, psychological, and social needs of HIV-infected students and their families are met.
- Meeting the psychosocial needs of classmates of a dying child with AIDS or of a child with an HIV-infected family member.

Universal precautions. It is likely that one will eventually interact with an HIV-infected student or staff member in the schools, whether or not that person is aware of his or her HIV status. From the extant literature, it is evident that school psychologists are not typically among those school personnel who need to know about a person's HIV status. According to the National Association of State Boards of Education (Fraser, 1989), the superintendent and the individual's personal physician are the only persons who *should* be informed of an individual's HIV status. A public health official should also be informed, but he or she does not necessarily need to know the identity of the affected individual. Disclosure of a student's HIV status to other school personnel need only occur if it is relevant to meeting the needs of the student. As presented earlier, transmission of HIV is extremely unlikely in normal school interactions. However, the Centers for Disease Control recommend that the usual universal precautions for infectious blood and body fluids be taken to prevent any chance of transmission (Fraser, 1989). These precautions are summarized in Figure 1.

Universal precautions pertain to blood or body fluids containing blood products. These precautions are described as universal because they should be applied to all persons, situations, or conditions regardless of HIV status. Thus, these precautions are not specific to HIV. They are as important in preventing other infections, such as hepatitis, as they are in preventing the transmission of HIV. In addition, they are extremely important in preventing opportunistic infections in the immune-suppressed HIV-infected child. Thus, universal precautions should be used in handling all body fluids. The school psychologist, other school personnel, and students should be familiar with universal precautions and should incorporate these precautions into everyday practice.

In addition to these universal precautions, it is imperative that all persons who work in the schools be educated regarding the modes of transmission of HIV and behaviors that can transmit the virus. In this way, informed proactive measures, rather than emotional reactions, can guide the decisions regarding the admission and treatment of an HIV-infected child in the school.

School-based AIDS education. As the prevalence of HIV/AIDS increases in the United States, so does the number of children and adolescents who live with or know an HIV-infected person. These increasing numbers of youth affected by HIV/AIDS intensify the need for AIDS education programs directed to this population, specifically school-based programs. As of March, 1992, 33 states and the District of Columbia had mandated AIDS education in their respective school districts and 14 states had recommended it (Haffner, 1992). Ohio, Tennessee, and Wyoming are the only states that neither mandate nor recommend AIDS education in the public schools. A state mandate is a requirement that all school districts provide this education, and it is usually accompanied by suggested curricula for AIDS education programs. A state recommendation is a suggestion that local school districts provide this education to the students, but they are not required to do so.

Unfortunately, the existence of a state mandate for school-based AIDS education does not mean there is a program in every school in the state. Furthermore, although the CDC and individual states provide guidelines for AIDS education in the schools, there is a lack of universally accepted standards for education programs. Therefore, actual programs vary widely among states, and even among districts within a state, in terms of which grade levels participate in the program, the program length and content, and training of the persons designing and implementing the program. In addition, program evaluation is inconsistent and often absent.

Studies of students' knowledge of HIV reveal that, although most surveyed children and adolescents know that HIV is transmitted through behaviors frequently identified in the media (e.g., sexual contact and sharing of needles for IV drug use), misconceptions regarding other modes of transmission, and negative attitudes or fears towards having a classmate with HIV are prevalent. For example, Holcomb (1990) found that 94% to 99% of 4th-graders surveyed knew that HIV is transmitted by sexual contact and sharing needles with someone who has AIDS. However, 36% to 56% also thought one can get AIDS from the virus particles in the air, by food prepared by someone who has AIDS, by being sneezed or coughed on by someone with AIDS, by mosquito bites, by sharing the same glass as someone with AIDS, and from public swimming pools. Of these 4th-graders, 51% believed that everyone is at risk for getting AIDS, and 59% "worry a lot" about getting AIDS. Seventy-one percent agreed they should receive education about AIDS and learn how it is spread.

Brown, Nassau, and Barone (1990) found similar results with 5th-, 7th-, and 10th-graders. Of these students, 90% to 98% knew the major modes of HIV transmission. However, 20% to 53% believed one can contract HIV by using a comb of an HIV-infected person, by having blood taken, and by mosquito bites. And 68% to 86% of these students reported they are nervous about AIDS; 51% to 53% favored keeping people with AIDS away from them. Overall 95% to 97% of these students favored AIDS education.

A study by Kann et al. (1991), involving a national survey of 9th- through 12th-graders, also found that, while 98% to 99% knew the major modes of HIV transmission, they held misconceptions about other modes of transmission. For example, 75% of these students thought HIV is transmitted by public toilets, and 12% thought they can reduce their risk of HIV infection by taking birth control pills. In addition 23% thought it was possible to tell if people are infected with HIV just by looking at them. Although 91% of the students believed they could not be infected by being in the same class with an HIV-infected student, only 51% thought students with AIDS should be allowed to attend their school, and only 56% indicated willingness to be in the same class as an HIV-infected student. While only about one-half reported having been taught about AIDS in school, almost all thought they should receive this education. In addition, these students were surveyed regarding their sexual practices. Fifty-nine percent of the students reported having had sexual intercourse; of those students, 40% reported having had four or more sexual partners. Therefore, a significant number of adolescents are at risk for HIV infection.

Although other studies have found a substantial increase in condom use among adolescents, the proportion of adolescents who are sexually active, and the proportion of adolescents engaging in unprotected sex, has also increased (Hingson, Strunin, Berlin, & Heeren, 1990). Thus, adolescents are at risk, not only for HIV infection, but also for other sexually transmitted diseases and unintended pregnancies. Compared to all other age groups in the general population, 10- to 19-year-olds have the highest rates of gonorrhea and syphillis (Miller, Turner, & Moses, 1990). Furthermore, if one is already infected with a sexually transmitted disease, he or she is at greater risk for contracting HIV during unprotected sexual activity.

Collectively, these studies indicate that, although children and adolescents can articulate the behaviors that spread HIV, they do not understand the modes of transmission. Therefore, myths about HIV transmission prevail. However, the vast majority of youth desire AIDS education. In addition, though they state that HIV-infected students should be allowed in the classroom, they do not want to be around them. Finally, though they can state the behaviors that transmit HIV, they continue to engage in these behaviors. In response to these findings, schools must provide education that facilitates understanding regarding the modes of HIV transmission, positive attitudes toward HIV-infected individuals, and changes in behaviors to decrease one's risk of HIV infection.

Community involvement. There is reason to believe that community-based AIDS education facilitates effective AIDS education in the schools. This may be accomplished by increasing community members' knowledge and positive attitudes about HIV/AIDS and facilitating communication at home between parents and their children regarding HIV-related issues. Community members' knowledge and beliefs about AIDS, and community response to AIDS education in the schools, are important considerations in developing an effective AIDS prevention program for children and adolescents. Over a decade after HIV was introduced into the United States, opposition to essential components of a comprehensive prevention program still exist. In June of 1993, a news release stated, *Miss America, . . . using her reign as a national platform to teach about AIDS, ran into censorship problems in her native Florida. Some school officials told her not to use the word "condom" while talking to students. Others forbade the name of the disease itself* ("Miss America," 1993).

Reluctance to allow AIDS education in the schools may result from lack of accurate information regarding HIV transmission, negative attitudes toward AIDS and persons with AIDS, or a general discomfort or fear regarding the disease. However, com-

FIGURE 1. Universal precautions for blood and body fluids.

1. Wear gloves when contact with blood or body fluids is likely.
2. Wash hands thoroughly with soap and water after removing gloves and after any contact with blood or body fluids.
3. Keep all cuts and open wounds covered with clean bandages.
4. Avoid smoking, eating, drinking, nail-biting, and all hand-to-mouth, hand-to-nose, and hand-to-eye contact when working in areas contaminated with blood or body fluids.
5. Clean all possible contaminated surfaces and areas with a 1:10 household bleach dilution or an approved disinfectant.
6. Clean up any spills of blood or body fuilds thoroughly and promptly, using a 1:10 household bleach dilution or an approved disinfectant.
7. Place all possible contaminated clothing and other items in clearly identified, impervious plastic bags.
8. Avoid sharing toothbrushes, razors, or other items that might transmit blood.
9. Avoid needlesticks and other sharp instrument injuries.

Note. From "Recommendations for Prevention of HIV Transmission in Health Care Settings" by Centers for Disease Control, 1987, *Morbididy and Mortality Weekly Report, 36*(25). Reprinted by permission.

munity involvement in AIDS education may ameliorate these circumstances. For example, Temoshok, Sweet, and Zich (1987) found that, among adults in three major cities, increased knowledge about AIDS was significantly correlated with decreased fear about AIDS and less negative attitudes about homosexuals. In addition, Sheridan, Humfleet, Phair, and Lyons (1990) found that an AIDS education seminar for school administrators, school nurses, and pastors significantly increased knowledge about AIDS, realistic perceptions of personal risk, and willingness to work with persons with AIDS.

Because many people associate moral and sexual issues with AIDS, there are families in the community who have negative attitudes toward AIDS education in the schools. The most likely alternative to school-based AIDS education for youth is AIDS education via parents or other family members. However, there is scant literature regarding family communication in the home about AIDS. Crawford et al. (1990) studied the effects of a multimedia-based presentation (television, newspaper, and newsletter) of AIDS education on 8th-grade students and their parents. Those 8th-graders and their parents who were exposed to the educational program and materials demonstrated significantly greater AIDS knowledge at posttest than those who were not exposed to the program components. In addition, at both pretest and posttest, those parents willing to participate in the education program reported they talked more with their children about AIDS and other sexual topics than did the parents who did not participate in the education components. However, in both groups, parents of 8th-graders who were identified as "at risk" for HIV infection (e.g., 8th-graders who engage in or know someone who engages in IV drug use, and/or who engage in or have friends who engage in sexual intercourse) had more difficulty discussing AIDS and other sexual topics with their children than parents of 8th-graders not at risk. These findings indicate that AIDS education directed toward the family enhanced parents knowledge of AIDS. However, communication about AIDS within the family was only enhanced if the child was not at risk.

Thus, based on these studies, community-based AIDS education can increase knowledge about HIV/AIDS, allay fears and facilitate positive attitudes toward HIV/AIDS and persons with HIV/AIDS, and facilitate communication in the home regarding HIV/AIDS. However, for children who are at risk for HIV infection and children whose parents are not willing to discuss AIDS at home, the importance of school-based AIDS education becomes even greater.

Communities with very low risk status may evidence more negative responses to AIDS education and persons with AIDS than a community aware of its high risk for HIV transmission. Therefore, to facilitate effective school-based AIDS education, the school psychologist must be aware of the community's risk status for the prevalence of HIV/AIDS. This can be accomplished by becoming familiar with the demographics of one's community. School psychologists must also be aware of the community's knowledge and attitudes regarding HIV/AIDS and persons with

HIV/AIDS, and the status of community-based AIDS education programs. Therefore, being actively involved in parent organizations such as the PTO and maintaining an active dialogue with public health personnel is important. School psychologists must also be knowledgeable of current medical interventions and their sequelae for HIV infection and AIDS, especially as they relate to children and adolescents. One should, therefore, become familiar with the pediatric AIDS literature and should develop a working relationship with a medical expert in the community who can serve as a resource when questions arise.

Guidelines for school-based AIDS education programs. Whenever one examines the various AIDS education programs, it is evident that the ultimate goal of school-based AIDS education is to get adolescents to abstain from sexual activity and illicit drug use. If an adolescent has already engaged in sexual intercourse or use of illicit drugs, school programs should enable and encourage discontinuance of these activities. For those adolescents who continue in these activities, school programs should provide education regarding protective behaviors recommended for persons at risk of acquiring HIV infection. Finally, there is a more recent trend to include social and psychological issues in the curricula, such as acceptance of HIV-infected individuals. This is an area where the school psychologist can make an important contribution.

The CDC, in consultation with other health and educational organizations, provides general guidelines to help school personnel develop AIDS education programs (see Figure 2). As discussed previously, it is extremely important that school personnel obtain broad community support and participation in the planning stage of program development. This ensures that the school's policies and programs regarding AIDS are consistent with community needs and values. The CDC recommends that community representatives who are involved in program planning include school board members, parents, school administrators and faculty, school health services, local medical societies, the local health department, students, minority groups, religious organizations, and other relevant organizations.

State guidelines and community values and needs should determine specific program content, degree of explicitness and teaching materials, format for education (e.g., lecture, guest presentation, skills training), and training procedures for AIDS educators. However, the CDC provides essential information to be included in any AIDS education program. This information is divided into three grade ranges designed to reflect differences in children's cognitive functioning at the various levels: early elementary school, late elementary/middle school, and junior/senior high school. Most of the current recommendations for AIDS education by various health and education organizations advocate for a similar developmental approach. Although these recommendations were not based on AIDS-specific research, recent research by Walsh and Bibace (1991) has found that children's conceptions of AIDS tend to follow a general developmental sequence, and it is similar to that of their conceptions of illness in general.

Because school psychologists may assist in the development and evaluation of school-based AIDS education programs, it is important that they are aware of age-related cognitive differences in children's understanding of illness. The following is a brief description of developmental differences in children's conception of illness and AIDS as identified by Walsh and Bibace (1991). In addition, the CDC recommendations for each developmental level are presented.

Preschool to early elementary school. Preschool and early-elementary-age children typically have an egocentric view of the world. They make little distinction between self and others. Therefore, they do not understand why one person has AIDS and another person does not. They focus on external, observable events and do not differentiate between cause and effect in explaining illness. Therefore, they tend to associate a specific behavior or person with AIDS without understanding the cause-effect relationship. In addition, they think in absolute terms regarding illness outcome. They have a limited understanding of the passing of time and do not understand the concept of long-term illness. In their view, illness causes death, which is immediate. Therefore, AIDS education for this age level should focus on reassuring the child of his or her remote chance of HIV infection. The CDC recommends that AIDS education focus on allaying children's fears of contracting HIV by explaining that HIV is difficult to get and that it does not commonly affect children.

Elementary school. Elementary-age children are less egocentric than younger children and can differentiate between self and others, although in somewhat absolute terms. They identify certain groups of people as those who have AIDS (e.g., "grown-ups," "homosexuals," "teenagers who do bad stuff"), and they differentiate themselves from these groups. In addition, they begin to differentiate between internal and external bodily events and cause-and-effect relationships. Although they have a limited understanding of physiology, they recognize physical symptoms, such as a headache or an upset stomach, and link them to an illness. The cause-effect relationship between a behavior and a physical symptom or illness is typically unidirectional and direct. They identify a specific behavior as causing AIDS, or a specific type of person as having AIDS, although they recognize that the behavior or type of person is not always associated with AIDS. The mechanism of contracting HIV (e.g., mode of transmission) is not understood.

FIGURE 2. Guidelines for school-based AIDS education programs.

1. Parents, teachers, students, and appropriate community representatives should be involved in developing, implementing, and assessing AIDS education policies and programs.
2. AIDS education should be developed as an important part of a more comprehensive school health education program.
3. Education about AIDS should be taught by regular classroom teachers in elementary grades and by qualified health education teachers or other similarly trained personnel in secondary grades.
4. AIDS education programs should help students acquire essential knowledge to prevent HIV infection at each appropriae grade.
5. AIDS education programs should describe the benefits of abstinence for young people and of mutually monogamous relationships within the context of marriage for adults.
6. Education about AIDS should be designed to help teen-age students avoid specific behavior that increases the risk of becoming infected with HIV.
7. Training about AIDS and AIDS education should be provided for school administrators, teachers, nurses, and counselors, especially those who teach about AIDS.
8. Sufficient program development time, classroom time, and educational materials should be provided for education about AIDS.
9. The processes and outcomes of AIDS education should be monitored and assessed periodically.

Note. From "Guidelines for Effective School Health Education to Prevent the Spread of AIDS" by Centers for Disease Control, 1988, *Journal of School Health, 58.* Reprinted by permission.

However, basic concepts of illness prevention are understood. According to the CDC, AIDS education should explain that viruses cause illness and decreased immunity. It should focus on general strategies for illness prevention such as hygiene in addition to causes and noncauses of HIV infection.

Junior high to senior high. Junior high and senior high school students view self as distinct from others. They also identify certain groups of people as those who have AIDS, and they differentiate themselves from these groups. However, they also recognize their relatedness to individuals in these groups even when they do not categorize themselves as belonging to the group. In addition, internal body processes and their relationships to external events are better understood. Therefore, they identify causes of HIV transmission and AIDS in relation to internal body processes. The CDC recommends that education at this level address detailed explanations of modes of HIV transmission and the specific effects of the virus on the body. Specific behaviors that transmit HIV should be presented, as well as protective measures besides encouraging abstinence from sexual intercourse and illicit drug use. In addition, the community can supplement school-based AIDS education by providing, outside of school, further information regarding HIV testing, counseling, HIV-transmission, or other related problems. These community resources should be made known to students as part of the school curriculum.

Evaluation of AIDS education programs. Evaluation of AIDS education programs is an essential component in prevention education. However, few programs have been formally evaluated. CDC (1988) provides nine criteria by which local and state personnel can evaluate the process by which schools are providing effective health education about AIDS:

1. To what extent are parents, teachers, students, and appropriate community representatives involved in developing, implementing, and assessing AIDS education policies and programs?

2. To what extent is the program included as an important part of a more comprehensive school health education program?

3. To what extent is the program taught by regular classroom teachers in elementary grades and by qualified health education teachers or other similarly trained personnel in secondary grades?

4. To what extent is the program designed to help students acquire essential knowledge to prevent HIV infection at each appropriate grade?

5. To what extent does the program describe the benefits of abstinence for young people and mutually

monogamous relationships within the context of marriage for adults?

6. To what extent is the program designed to help teen-age students avoid specific types of behavior that increase the risk of becoming infected with HIV?

7. To what extent is adequate training about AIDS provided for school administrators, teachers, nurses, and counselors — especially those who teach about AIDS?

8. To what extent are sufficient program development time, classroom time, and educational materials provided for education about AIDS?

9. To what extent are the processes and outcomes of AIDS education being monitored and periodically assessed? (p. 146)

In addition, outcome evaluation should include measures of children's and adolescents' knowledge regarding HIV/AIDS, as well as measures of application of this information (e.g., decreased sexual activity and IV drug use among adolescents, and increased use of protective measures during sexual activity and IV drug use). Although studies have shown that children and adolescents can state the high risk behaviors associated with HIV infection (e.g., sexual intercourse, sharing IV drug needles), no education programs to date have been shown to significantly reduce these behaviors. There are numerous AIDS knowledge questionnaires currently available. The reader is encouraged to consult Brown et al. (1990) as an example. In addition, Kann et al. (1991) provide examples of self-report surveys that have been used to assess behavior change.

BEST PRACTICES IN DEALING WITH HIV IN THE SCHOOL

As early as 1988, the National Association of School Psychologists (NASP, 1988) presented a position statement regarding AIDS. This encourages all school psychologists to become knowledgeable about the disease and facilitate the provision of AIDS education and related services to students. Specifically, NASP advocates that the school psychologist, in collaboration with other professionals:

1. Assist in the development, implementation, and evaluation of AIDS education appropriate for age, gender, ability level, and cultural group.

2. Facilitate parental involvement in AIDS education in the school, home, and community.

3. Participate in the decisions about educational and related services for an HIV-infected child.

4. Address the educational and psychological needs of students, parents, and school personnel who are concerned about school attendance of a student known to be HIV infected, at perceived high risk of infection, or who has a family member with HIV infection.

5. Provide supportive counseling for students who have a family member or friend with AIDS, students at high risk or perceived high risk of HIV infection, or students with AIDS.

6. Help teachers, administrators, and parents recognize and address the general feelings and personal concerns regarding HIV.

7. Work with other education and support personnel to establish and maintain appropriate AIDS-related behaviors and attitudes in students.

Consistent with the NASP recommendations, the following suggestions will assist school psychologists to become proactive members of the collaborative team that must address HIV-related issues in school:

1. School psychologists need to be aware of the epidemiology of HIV. The CDC periodically updates epidemiology statistics in the *HIV/AIDS Surveillance Report*. It is important to assume that HIV is present in every community. Adolescents, in particular, are known to be at increased risk for HIV infection. Thus, each district must make a commitment to address HIV- and AIDS-related issues in their schools.

2. School psychologists should become familiar with the school's policy and guidelines regarding the presence of HIV-infected students and staff in the school. If this policy has not been established, school psychologists should advocate for its creation. This policy should be established before an HIV-infected student is known to the district.

3. Related to the above issue, school psychologists should become familiar with legal issues surrounding school attendance of infected children. An HIV-infected child cannot be denied admission to school on the basis of his or her HIV status. In addition, this child has a legal right to privacy. In most circumstances, this means that only the school superintendent and a pubic health officer have a right to access the information regarding the student's medical condition. In other words, it is not necessary for most school personnel to know the identity of an HIV-infected child.

4. School psychologists should become familiar with the physical and cognitive sequelae of HIV/AIDS. The current literature indicates that memory, attention, language, and motor abilities are adversely affected by HIV/AIDS. However, pharmacological intervention with AZT has resulted in increased Verbal and Performance IQ scores (Levenson & Mellins, 1992). The extent and permanence of the effects of HIV-infection and pharmacological treatments are not fully known. Therefore, a multidisciplinary team approach involving close collaboration with teachers, occupa-

tional therapists, physical therapists, speech therapists, the school nurse, and other professionals is necessary in assessing and monitoring children with HIV/AIDS.

5. School psychologists should become familiar with the social-emotional correlates of HIV/AIDS. Parental illness and death, stigma-induced isolation from peers and adults, as well as the prospect of facing disability and death, will affect the HIV-infected child's functioning at home, school, and in the community. Siblings of HIV-infected children, and noninfected children of parents with HIV, also face similar psychosocial trauma. Supportive counseling is considered a critical component in school psychologists' comprehensive approach to the AIDS challenge.

6. School psychologists, as well as all students and other school personnel, should be familiar with universal precautions for blood and body fluids. These precautions should be incorporated into everyday practice.

7. School psychologists should advocate for community-based HIV education. Research in this area documents that AIDS education in the school can be enhanced by community-based AIDS education and support services. School psychologists should become actively involved in parent and community organizations to accomplish this end.

8. School psychologists should establish working relationships with key public health and medical professionals in the community who work with HIV-infected patients.

9. School psychologists should contribute to the development and implementation of school-based AIDS education by consulting with the school's health educators and nursing personnel. They should advocate that AIDS education be infused into the curriculum at all grade levels and that it be age-appropriate. This includes allaying the fears of preschool and young elementary-age children, providing elementary school children information about hygiene and illness prevention, as well as causes of AIDS, and providing specific information to the junior and senior high school students regarding modes of HIV transmission. For these older students, this involves addressing specific behavior changes to decrease their risk of HIV infection. In addition, HIV education must address the social and psychological sequelae of the disease. Finally, school psychologists should use their expertise to facilitate positive attitudes of students and school personnel toward HIV-infected individuals.

SUMMARY

In most schools in the United States, AIDS education promoting sexual abstinence among adolescents is the typical educational response to the AIDS epidemic. However, AIDS education must not only target children at a much earlier age, but also address attitudes towards infected individuals. With the increasing number of children who are directly or indirectly affected by HIV, there will be a greater demand to meet the special needs of these students. This means that schools and communities must work together. The seriousness of the HIV epidemic requires that every school psychologist be active in preventive education addressing HIV transmission, in ameliorating the repercussions of HIV in the school, and in meeting the needs of affected students.

Best Practices in Planning for Emergency Management within the Schools

Theresa Hubbell Jozwiak
Carol Johnson
Elaine Petersen
Loess Hills (Iowa) Education Agency 13

Often in the literature on crisis intervention, authors mention the need for developing pre-crisis plans and the importance of identifying community resources for use during and after a crisis event. The focus of the writing (Nelson & Slaikeu, 1984; Poland & Pitcher, 1990; Sandoval, 1987; Smead, 1985) however, tends to describe the steps and skills necessary to doing crisis intervention services in the schools. The process for developing the district-level response plan appears to have received little attention until recently (Pitcher & Poland, 1992). The intent of this chapter is to provide school psychologists and other pupil services personnel (social workers, guidance counselors, and nurses) a general process to facilitate developing a district-level or building-level emergency-management plan. This process is presented in a problem-solving format, as a series of questions to be answered first by a building or district core team and then by a larger, multiagency emergency-management planning committee.

OVERVIEW

Emergency planning is proactive. Planing allows the emergency to be managed in an effective, efficient manner rather than mismanaged through benign neglect resulting in chaos. The need for schools and community to collaborate in establishing a community-wide plan is critical because in an emergency situation the *two* systems become *one*. Community agencies providing a variety of safety, medical, and emotional well-being and relief services will be called upon during an emergency. When all the players understand and own a piece of the plan there will be a more effective response to the emergency. Quick and efficient response reduces injury, loss of life, and emotional trauma for the victims. What better reason for emergency planning than to protect our children!

Although central information centers are not collecting data regarding school emergencies, there are indicators of an increasing need for emergency management planning. Everywhere in this country students and adults are exposed to natural disasters, such as tornadoes, hurricanes, floods, and the like. In addition, there is overwhelming documentation (National School Safety Center, 1993) that the schools in this country are the scenes of "unnatural" disasters (fires, vehicular accidents, etc.) and violent behavior.

In 1990, the nation experienced a record juvenile violent-crime arrest rate. Between 1980 and 1990, murder committed by juveniles increased 87% and aggravated assault by 64% (Uniform Crime Reports, 1991).

- One-half of all violent crimes (homicide, forcible rape, robbery, or aggravated assault) against teenagers occurs in school buildings, on school property, or on the street. Most of the crime involving weapons occur on the street rather than in the school building (37% compared to 12%; Bureau of Justice Statistics, 1991).
- Children do not feel safe within their neighborhoods or schools. Each day 135,000 children bring a gun to school (National Children's Defense Fund, 1993).
- Only 37% of the violent crimes taking place in school buildings and 32% of those on school grounds are reported to the police (Bureau of Justice Statistics, 1991).

Regardless of whether the disaster is the result of natural or unnatural causes, the effects are differentially experienced by members of the community. Planning must include both management of the emergency situation and an immediate response of crisis intervention.

The literature on crisis intervention defines *crisis* as a time when "an individual is faced with any problem he/she sees as serious and that has no immediate solution. The problem might seem hopeless because the individual is unable to solve the crisis with their customary problem solving skills" (Smith, 1978). A crisis is often the result of an emotionally hazardous situation in which the individual is unable to call upon his or her emotional supports or in which he or she loses confidence to act effectively (Sandoval, 1987).

While the literature on crisis intervention talks about responding to and providing services in an emergency situation, emergencies and crises are not the same. An *emergency* is a potentially hazardous event which might trigger crisis for some individuals and not others. Some individuals might not find the situation threatening and others might find that they can cope regardless of the hazards and problems (Smead, 1985). It implies a possible need for a systemwide or multisystem response as compared to the individual focus of crisis intervention.

Emergency Management is a comprehensive, systematic approach to handling unexpected hazardous events. The ultimate goal is to ensure the safety of individuals and to minimize the trauma of the hazardous situation. An emergency management approach includes a planning phase, the response during the emergency situation, and the identification and provision of services for long-term needs (Poland & Pitcher, 1990).

As indicated in the crisis intervention literature (Poland & Pitcher, 1990, 1992; Smead, 1985), the traditional point of entry for pupil services personnel is following an emergency situation to provide individual crisis-intervention services. Crisis intervention is viewed as occurring at three levels: primary prevention, secondary intervention, and tertiary prevention (Poland & Pitcher, 1992).

Primary prevention includes those activities designed to prevent or minimize emergency situations and the resulting trauma and crises. These might include curriculum modifications to teach children safety rules and to recognize potential hazards, and ways and timing to respond in a specific crisis situation. Making and testing the emergency plans for how a district or building would respond is also a primary prevention activity.

Secondary intervention, as developed in Caplan's (1964) model, are those activities designed to minimize the escalation of the crisis through quick response. These activities include conducting drills (Poland & Pitcher, 1992; South Dakota State Department of Military and Veterans Affairs, 1991) to have staff and/or students practice the emergency plans. This practice allows the individuals to respond quickly in an emergency situation and to carry the knowledge into other situations and environments. It also includes the immediate response of the pupil services personnel to work with children and adults to manage the effects of the hazardous situation so that individuals are able to cope more productively.

Tertiary prevention, or postvention, are those activities designed to provide follow-up assistance to reduce the negative long-term psychological effects on those experiencing a traumatic event. Follow-up activities might include crisis counseling provided either by the pupil services personnel or through referral to community agencies. Long-term follow-up counseling might be necessary for some individuals and is often provided by community agencies.

Emergency-management planing activities provide a base from which pupil services personnel can be part of the team to identify how to respond quickly in an emergency situation. Early response increases the likelihood that fewer children are traumatized by an event (Poland & Pitcher, 1990). The children most traumatized are those most directly affected by the hazardous event (Nader, Pynoos, Fairbanks, & Frederick, 1990). Early response facilitates minimizing the trauma for children and adults. Emergency-management planning also provides the network for follow-up services.

BASIC CONSIDERATIONS

School psychologists and other pupil services personnel (social workers, guidance counselors, and nurses) have many roles in emergency management. These roles include (a) planning for emergency management, (b) developing crisis or emergency response teams, (c) providing direct crisis or emergency services during the event or immediately after, and (d) providing postvention services to assist the victims to cope with the long-term effects. To effectively work with Emergency Response teams, the school psychologist and pupil services personnel need a knowledge base in crisis intervention strategies for

- Individuals and systems (Poland & Pitcher, 1990; 1992; Sandoval, 1987; Smead, 1985).
- Methods for conducting debriefing groups (Lazarus & Howard, 1993; Thompson, 1990).
- Posttraumatic stress syndrome (Lipovsky, 1991; Nader et al., 1990).
- Strategies for addressing the grief process (Morrow, 1987; Slaikeu & Lawhead, 1985).

This knowledge base permits school psychologists to provide individual and group crisis counseling or to advise others for providing the support services needed. It also provides the base from which to advocate for a comprehensive emergency-management program including planning, practices and drills, and follow-up services.

To be an effective advocate for emergency planning, the school psychologist and pupil services personnel must be familiar with the crisis- or emergency-response plans existing in a building or district. Identification of community resources and contact people within the community organizations (Sandoval, 1985) for long-term follow-up services is quite often a task which falls to the pupil services personnel because other educators have little contact with the medical and private counseling sector.

The building administrator is the key to any comprehensive plan within a building. As a knowledgeable professional, often outside the direct supervision of a building administrator, the school psychologist is in an excellent position for taking an objective look at what is working, what is not, and what is available in an effort to meet the emotional needs of the students and staff. Participation on a response team in a crisis or emergency situation and in postvention is helpful for understanding what is covered by the current plans and what needs to be included in comprehensive planning. It is critical to obtain administrative support for emergency management planning.

Because of the importance for the planning process to involve various community organizations, an understanding and appreciation for differing, mandates, perspectives, and policies is needed to facilitate coordination and collaboration for emergency management. Basic skills in group process and facilitation are necessary to accomplish the work of such a diverse committee. School psychologists and social workers are often trained in these skills, thus making coordination of the committee's efforts a reasonable role for either or both.

Part of a comprehensive emergency-management plan is to provide inservice and drills for students, teachers, and other staff as determined appropriate. Assisting with this inservice and practice is an appropriate role for the school psychologist and the pupil services personnel, particularly regarding the emotional needs of individuals during traumatic events.

Thus the school psychologist and the pupil services personnel have key roles as advocates of comprehensive planning and services, as facilitators of the multiagency planning process, as trainers of the plans, and as direct service providers.

BEST PRACTICES

All to often planning for an emergency situation, which might or might not occur, is the last thing on a person's "to do list." Historically (Poland & Pitcher, 1990), the opportunity to develop an emergency response plan has followed an emergency for which there had been little organized response. Most crisis- or emergency-response programs recommend a debriefing meeting for the response team. This often provides the foot-in-the-door opportunity for the school psychologist and other pupil support personnel to advocate for additional planning.

One useful strategy for expanding the concept of emergency management is introducing "what if" scenarios into formal or informal discussions. During the training of emergency-response teams, one might expand their paradigms beyond suicide or accidental loss of life through the use of such scenarios. A script might be similar to the following two examples:

> In our district this past school year eight fires were set in school buildings by students experimenting with matches or other combustible items. In most of these cases the fire department was not called immediately because the building staff opted to extinguish the fire themselves. None of these fires got out of hand or resulted in evacuation of the students. Now close your eyes and picture this: "What if" the fire continues to burn, spreading to more flammable materials? The students and staff are evacuated from the building using the standard fire drill procedures. By the time the fire department arrives, the fire has spread to several nearby classrooms. The students are not able to return to the building for the remainder of the day. It is January and the temperature is five degrees above zero. (Remember, fire drill procedures usually call for the students and teachers to leave the building without their coats.) What will you do? Where will you shelter the students and their teachers until dismissal?

> In the past few years, our city has seen an increase in gang-related violence, primarily among our youth. While on the playground during recess, an elementary student was shot by a stray bullet from a drive-by shooting. In another incident, a high school student was shot while walking home from school. Now, close your eyes and imagine: "What if" a person was in the building with a gun? What will you do to minimize the risk to the greatest number of students? What do you need to consider?

Because there is a natural inclination to believe certain events would not happen in "my building" or "my district," finding opportunities to introduce relevant information describing the need for emergency planning is important for developing awareness. It is also beneficial to use information from local sources that indicates an emergency *can* happen within the local setting.

As with many planning efforts, a *core team* needs to be identified and organized to serve as a coordinating body for planning activities and a catalyst for implementing the plan. The core team at the building level consists of a building administrator, a teacher, a parent, and at least one representative from the pupil services personnel. Logically the members of the core team coordinate and organize an expanded emergency-planning committee. They provide the link between the community emergency plans and the building's application of the plans.

One of the primary tasks of the core team is to identify persons to serve on or advise the emergency-planning committee. Because the school belongs to the community, the community must be an integral part of the planning process. Representatives of community organizations who might be invited to participate on the planning committee include law enforcement officials, fire fighters, businessmen, health care professionals, community religious leaders, media representatives, utilities representatives, civil defense personnel, Red Cross officials, and whoever else has the interest and time to assist the school or district in developing an emergency-management plan. Additional school district or building personnel who might be included on the committee are a board representative, school nurse, building custodial staff, bus driver, and/or district administration staff.

Because planning is essentially filling the gap between what is already available and what is needed, the school and community people need to meet together at least once to discuss and identify:

1. What are the potential emergencies and what are the probabilities of their occurrence in your geographic area/building?
2. What are the community and school disaster plans? How do the plans fit each other and what are the roles of the representative organizations in a variety of emergencies? What do school personnel do until emergency services arrive?
3. What are the gaps between what we have and what we might need for the potential emergencies identified in question one? In order to identify the "gaps" in the existing plans, the planning committee might consider the following questions:
    a. Where could we evacuate students if necessary? How do we get students there? What is an alternative route?
    b. What needs to be done to confine students if necessary? Where should they be confined given the possible emergency?
    c. How can students be cared for until emergency personnel can arrive or until parents can arrive to assume responsibility for their child? Under what circumstances might the students be released without direct contact with the parent?
    d. How will students be accounted for? What is the procedure for releasing them? How might this differ in varying circumstances?
    e. How can students be transported to their homes if not released directly to their parents?
    f. How should parents be informed and updated about a specific emergency situation?
    g. What alternative communication resources are available?
    h. What is your district's media policy? How can you keep the media updated? Who are the prescribed district contact people?
    i. How can others who must be kept informed be updated and apprised of the situation as needed? How do we identify an alternative coordinator of a local-building response plan if the designated administrator is unavailable or hurt?
    j. How should external emergency response organizations be contacted? At what point?
    k. How do we reassure those involved in protecting the children (I.e., teachers, counselors, etc.) about the welfare of their own families when the emergency is district wide or even if they have family members in a different part of the same building?
    l. Is an emergency box needed? This would be a portable, fire-proof box with critical information which might be needed during an emergency or evacuation of a building. If so, what might be put in it (e.g., class rosters — teachers typically do not take their class rosters with them when evacuating for fire drills, student emergency phone contacts, district emergency policy, etc.)? Where would it be kept? Who keeps the information current? Who is responsible to take it from the building and under what emergency conditions?
    m. How can the need for water, food, and bathroom be met under each disaster/emergency situation?
    n. What are building barriers or hazards? What are classroom barriers or hazards?
    o. Where are plans of the building stored? (These should include shut-off valves.)
    p. Is our insurance adequate? Is our inventory adequate? Are records (student, personnel, and property) in fire-proofed files? Are media materials insured and properly protected?
    q. What measures are needed to protect the building from looters?
    r. What training is needed within the district/local building? To whom will this training be provided?
    s. What preparedness and hazard awareness information might be included in the curriculum for students?
    t. How involved can/should the students be in preparing the plans for their building/the district?
    u. How could the planning team practice the plans to determine the effectiveness and efficiency of the plans? Which plans are most likely to be needed and therefore, most likely to require rehearsal?

Initially the Planning Committee's work can seem overwhelming. One very helpful document is the *Emergency Planning Guide for South Dakota School Administrators*, available through the South Dakota State Department of Military and Veterans Affairs, Pierre Division of Emergency and Disaster Service. This guidebook is designed to help develop emergency plans for schools and gives detailed step-by-step descriptions of how to develop the team and the plans. Although there might be existing written outlines for emergency management, it is critical for school and community representatives to have discussions about each organization's roles and responsibilities in various emergency situations. Only through this discussion can the "players" know what can be expected from one another.

Obviously, the written plan cannot be operationalized within the building unless all staff members are familiar with specific plans and have the skills to do what is expected of them in an emergency situation. The core team, with the assistance of community representatives, identifies training needs and appropriate resources (people, time, and topics) for providing the training. Most comprehensive plans (Manitoba Department of Education and Training, 1991; South Dakota State Department of Military and Veterans Affairs, 1991) recommend knowledge of first-aid for all teachers and CPR for selected individuals in addition to training for *all staff* in implementing the plans. Be sure that there are individuals within each building trained in first-aid, CPR, and crisis-intervention skills — understanding loss and grieving, facilitating debriefing groups, knowledge of the effects of posttraumatic stress, and referral to external support agencies. Each of these areas require skills above and beyond implementing the plan and most professional preparation sequences have not included the development of these skills. These skills, like any new skill, require use to develop expertise and maintain confidence. If situations do not arise in which the skills are used, pupil services personnel will need to obtain information and practice through literature review and workshops. One of the best methods for acquisition and maintenance of skills is through practice and drills.

The importance of drills/practice cannot be over emphasized. The purpose of the drill is to help students and staff learn to react immediately and appropriately to an emergency. Without the emotionality associated with a traumatic event, drills will highlight the areas needing change and allow them to be made. The core team might choose to request a community safety agency to observe the drill to assist in identifying the areas of need and to make recommendations for improvement. Drills encourage "what if" thinking to improve the preventative measures of the plan and support the purpose for emergency planning.

Using the planning committee's recommendations, the core team makes the decisions about the timing, the breadth, and the content of the drill. Questions the core team might consider include

1. What is the probability of a particular emergency occurring (Sandoval, 1987)?

2. What would be the impact of this emergency if it occurs even once?

3. Should this drill include all building staff, or students and staff, and/or community participants?

For additional information on how to structure drills, consult South Dakota (1991), Poland and Pitcher (1992), and Pitcher and Poland (1992).

Emergency education as a curriculum component will help students manage themselves in an emergency, not only at school, but at home as well. Their training in how to remain calm and to know what to do will help them deal effectively with emergencies in their families and communities. This information provides a lifetime benefit (Manitoba, 1991) and is carried over when they establish their own families.

Information and experience are the keys to protection and have been demonstrated to reduce the trauma associated with many hazardous situations.

SUMMARY

School psychologists and other pupil services personnel have been working to develop crisis-intervention teams to assist in minimizing the long-term negative psychological effects of traumatic events. Now is the time for these same individuals, who have the background in consultation and group facilitation, to assist schools in recognizing the need for comprehensive emergency-management plans. Natural disasters (like Hurricane Andrew), man-made emergencies (like Desert Storm), and the violence in our schools exist and threaten the well-being of our children. The literature has many examples of the benefits of rapid response. Emergency-management planning eliminates the gaps in building and district plans to train adults and students to respond appropriately in emergency situations, to access emergency response organizations and crisis intervention teams quickly, and to identify and refer individuals needing intensive follow-up services. Planning ensures the safety of students and staff and reduces the negative aftereffects of trauma for the participants in hazardous situations.

ANNOTATED BIBLIOGRAPHY

Pitcher, G., & Poland, S. (1992). *Crisis intervention in the schools.* New York: Guilford Press.
The authors discuss the theoretical basis for crisis intervention in the schools, and information on specific crises often encountered is provided. Various roles of the school psychologist ranging from consultant to trainer to interventionist are presented in detail. Information to assist in establishing a district-wide management plan is also included.

South Dakota State Department of Military and Veterans Affairs. (1991). *Emergency planning guide for South Dakota school administrators.* Pierre, SD: Division of Emergency Disaster Services.
The guidebook is designed to help principals, teachers, staff, parents, and students develop an emergency guide for their school. Besides preparing a response plan, emergency planners must identify hazards, conduct drills, and involve the school community in planning to provide care and shelter for students until they can be reunited with their parents. Appendices contain planning forms and worksheets, a teacher's package on drills, safety information, and information on children in disasters.

INFORMATION RESOURCES

Federal Information Centers, 1-800-788-2800. One toll-free call accesses seven different federal information centers: National Clearinghouse on Alcohol and Drug Information (NCADI), Drug Information and Treatment Line, Drug-Free Workplace Helpline, Drugs & Crime Data Center and Clearinghouse, Drug Information & Strategy Clearinghouse, National AIDS Clearinghouse, and National Criminal Justice Reference Service. The information centers generally have multilingual and multimodal information in the specific area of interest. The materials are usually free of charge or at minimal cost.

Federal Emergency Management Agency (FEMA), FEMA Publications, P.O. Box 70274, Washington, DC 20024. (202) 646-3484.
FEMA offers a variety of information – all of it free of charge – that can assist with emergency planning. Information is available for business and industry and for family preparedness. Information specific to schools is limited to tornadoes. If information is requested, it comes in a variety of formats (i.e., print-English and Spanish, braille, audio and video). For further information, call Ralph Swisher, Program Manager for Emergency Public Information in FEMA's Office of Emergency Management, (202) 646-3561.

National Crime Prevention Council, 1700 K Street, NW, Second Floor, Washington, DC 20006. (202) 393-7141.
The council has materials at different developmental levels which would be appropriate for curriculum use. The council sponsors the "Take a Bite Out of Crime" program and other neighborhood and community programs to prevent crime and improve public safety.

National School Safety Center, 4165 Thousand Oaks Blvd., Suite 200, Westlake Village, CA 91632. (805) 373-9977.
The N.S.S.C. is supported by the United States Department of Education and Criminal Justice. The Center provides many written and video materials. Call or write for a complete listing.

Regional Educational Laboratories and Regional Centers for Drug-Free Schools.
These agencies provide print and video resources such as curriculum, model programs, and proven community strategies. They also provide technical assistance for creating violence prevention programs, school safety training for personnel, and gang awareness and violence prevention workshops. Contact your state department of education office to obtain the phone number and address for the regional center serving your local area. For example, in Iowa, planning committees would access the North Central Regional Education Laboratory's Minneapolis office.

State and County Civil Defense Offices.
These organizations have local and state disaster and evacuation plans. They also usually have information on alternative communication systems.

Best Practices in Facilitating Peer Tutoring Programs

Enedina García-Vázquez
Stewart Ehly
The University of Iowa

OVERVIEW

The use of the word "tutor" can be traced back centuries to societies in which more privileged members provided education in the home to their children (Gordon, 1990). More recent use of the term "peer tutor" reflects the modern perception of the importance of peers as influences on children's development. Peer tutoring represents one form of children's helping relationships, one that has been investigated extensively in the past three decades (Foot, Morgan, & Shute, 1990) and recommended to improve student productivity (Walberg, 1984). In *Best Practices in School Psychology–II*, Peterson and Miller (1990) list peer tutoring as a viable peer-influenced academic intervention. Class-wide peer tutoring (Delquadri, Greenwood, Whorton, Carta, & Hall, 1986) and class student tutoring teams (Maheady, Sacca, & Harper, 1988) have also received favorable consideration in the literature.

Thus, the use of the terms "tutor" and "peer tutoring" has varied over time and throughout the literature. For the purposes of this chapter, discussion will center on activities that involve children helping other children to acquire specific knowledge or skills while working one-to-one under the guidance of the teacher or support professional. While the history of tutoring extends well beyond the limits of children working with their peers, this chapter features activities that utilize the resources of a typical classroom.

Another distinction of terminology is worth presenting, that between cross-age and same-age peer tutoring. Information on cross-age arrangements differs little from that of same-age or true peer combinations as indicated later in this chapter. Both options can be utilized within a school or, in the case of cross-age programs, involve children from several schools. The school psychologist as problem solver can be the agent who alerts teachers to the potential benefits of peer tutoring and who, for larger scale programs, links clusters of teachers together into working groups.

A basic consideration that must be addressed is: Why use peer tutoring? What does peer tutoring offer that other instructional options cannot provide? Simply stated, peer tutoring builds on the social and instructional resources of the classroom, school, or district to address fundamental academic needs of children. In the school reform literature, writers such as Perkins (1992, see Annotated Bibliography) argue for the importance of embedding learning activities within natural and available social networks in the school. Peer tutoring, along with cooperative learning and other peer-mediated activities, provides an effective means by which to introduce students to concepts, skill-building or practice materials, and even social-skills content that can supplement the actions of the teacher and support professional — always with student learning as the intended outcome. Perkins' (1992) proposal for a community of learners working with their peers echoes the early 19th century "monitorial system" created by Joseph Lancaster in England. A modern application involving an entire school in a tutorial community was proposed by Melaragno and Newmark (1969/1970).

Again returning to the basic question — why peer tutoring instead of other instructional options? Gerber and Kauffman (1981), while supporting peer tutoring, caution that the peer tutor is not a free resource. Time to select, train, monitor, and evaluate the tutor and learner (often referred to in the literature as the *tutee*) requires the teacher's time and energy. Drawing both partners away from other activities must result in gains for both parties to convince parents that time has been well spent. Gerber and Kauffman (1981) consider peer tutoring to be a rational choice for teachers "*if* the resulting educational outcomes are improved with the expenditure of the same amount of teacher time, or *if* the educational outcomes remain the same with an investment of less time" (p. 162).

The following sections highlight the available literature to justify consideration of peer tutoring as a "best practice" strategy within schools, an option that school psychologists can recommend, develop, and implement knowing that the intervention is likely to produce desirable outcomes.

BASIC CONSIDERATIONS

Peer Tutoring Options

Programs involving peer tutoring have been conducted with virtually every combination of cross-age pairings, of tutor-tutee ability levels, with volunteer and paid participants, in all school subjects, and within many forms of community and school programs. Ehly and Larsen (1980) reported examples of high school and junior high school students tutoring elementary children, older elementary students working with young children, and multiple examples of projects involving content from every academic subject, including science and social studies. Studies in the 1960s and 1970s often focused on gains for tutees, with advantages noted for many tutors. Later efforts to assess the growing literature on tutoring's effects identified benefits for both parties (Cohen, Kulik, & Kulik, 1982).

More recent studies conducted with elementary school students have reported academic benefits for all participants. An abundance of studies has been done involving children from special education classes serving as tutees. In general, research has shown that peer tutoring is a viable alternative to teacher-directed instruction to increase the academic performance of students, whether assigned to a general education or a special education classroom. In addition to gains in achievement, recent studies have targeted social gains from peer tutoring interventions. Osguthorpe, Eiserman, and Shisler (1985), for example, paired fourth through sixth grade students who had been assigned a label of "mental retardation" with peers from regular education classrooms. Eiserman (1988) paired students assigned a learning disabilities label with regular classroom peers who served as tutees. Both studies reported gains in the participant's social attitudes on school and learning.

While application of peer tutoring arrangements is much more commonly used with a small number of dyads, other options are available. Although many of the reported instances of same-age peer tutoring have targeted academic gains, Greenwood et al. (1984) demonstrated that class-wide tutorials are effective. Class-wide peer tutoring produced higher weekly test scores and more student responding than did teacher-run procedures. The authors noted that the lowest performing students in the class experienced the greatest benefits from their experiences.

Class-wide peer tutoring provides opportunities within the classroom for students experiencing difficulties to be tutored in a structured way by students who have mastered those skills (Phillips, Hamlett, Fuchs, & Fuchs, 1993). Most recently, Phillips and colleagues (1993) combined class-wide curriculum-based measurement with class-wide peer tutoring to increase academic skills in mathematics. This combination yielded a data-based system that provided structure to the peer tutoring program, assisted in instructional goals, and significantly increased math skills. While gains were more notable for students identified as low achieving and average achieving than students with learning disabilities, the overall conclusion was that integrating curriculum-based measurement with instructional strategies such as peer tutoring positively influences general education (Phillips et al., 1993).

Greenwood, Carta, and Kamps (1990) support peer-mediated instruction such as peer tutoring as a supplement, even an alternative, to teacher-mediated instruction. Not only do peer-mediated arrangements relieve the teacher of direct instructional responsibilities, they offer more one-to-one contact between instructor and learner. Gerber and Kauffman (1981) cite several studies that support the viability of peer tutoring as an instructional alternative for teachers. It is evident that all tutoring options (same-age, cross-age, class-wide) can lead to positive academic and social outcomes for all participants.

Practical and Ethical Considerations

Arrangements such as peer tutoring are not without costs, both calculable and ethical. The costs of teacher time and energy in arranging for and monitoring all phases of tutorials have already been mentioned. When school psychologists consult with teachers and provide assistance with any phase of arrangements, teacher time and energy are important considerations. In addition, materials developed by school personnel, students, or parents for peer tutoring activities impose very real costs on the parties involved.

Out-of-pocket expenses for peer tutoring can be supported by the school district, PTA/PTO, or any of a number of funding sources. Although the obvious expenses of tutorials can be calculated, the ethical costs may be more difficult to estimate. Greenwood, Carta, and Kamps (1990) raise three areas of ethical concern relevant to peer tutoring: accountability, competence, and informed consent. Each concern must be addressed to be consistent with the Principles for Professional Ethics of the National Association of School Psychologists (Appendix I).

School psychologists can be valuable allies to teachers in evaluating the ethical costs of tutorials. For example, the psychologist can assist in evaluating the benefits that the tutor and tutee are deriving from activities. The literature would suggest that academic gains are quite possible; affective changes are less certain. The psychologist can work with the teacher or the students to develop and implement monitoring and evaluation procedures to place within tutoring arrangements.

Often parents challenge the alleged benefits from peer tutoring. Parents of tutors selected from high-ability classroom groups question the value of tutorials for their children's academic development. When tutees are selected from low-ability groups, their parents often unfavorably compare tutorials with teacher-directed instruction. The psychologist with a knowledge of the literature can respond to many such challenges and be available to work with school personnel to ensure adequate implementation of procedures that will lead to the best possible outcomes.

The concern relating to competence centers on the tutor's ability to rise to the requirements of the role. Consensus on the importance of training and monitoring peer helpers exists across the literature (Greenwood, Carta, & Kamps, 1990). Ehly and Larsen (1980) recommend evaluating tutor ability for mastering all requirements of the role *before* allowing dyads to meet.

Finally, the issue of informed consent must be addressed. Parents are important parties to any requests for permission to involve children in special activities; the students themselves must be afforded the opportunity to consider the potential benefits from working with peers and be permitted to enter or retire from activities without coercion. The psychologist and teacher must be sensitive to participants' concerns relating to reactions from the peer group: Peer tutorials may meet an adult's standards for productive work but, by singling out individual students, may fail miserably to motivate students to become involved.

BEST PRACTICES

Research on Academic Outcomes

Numerous studies have been conducted examining the effects of peer tutoring on the tutor, tutee, academic outcomes, and even social benefits. However, the majority of the investigations have focused on academic benefits. The research has shown that tutoring programs have significant benefits on students' academic achievement, whether in the tutor or tutee role. Not as conclusive, though, are the benefits on affective aspects.

By the late 1960s reviews to consolidate findings and examine overall effects were being conducted. In 1969 Rosenshine and Furst reviewed the literature on tutoring programs and concluded that these programs contributed to the academic growth of both the tutee and the tutor. However, according to the authors, these results were noted only in well-structured and cognitively oriented peer programs. Additionally, Rosenshine and Furst (1969) stated that review methods were lacking a stringent scientific approach. With the inception of the meta-analysis procedure, more powerful methods were available to employ in reviewing overall effectiveness of peer tutoring interventions.

Hartley (1977) applied meta-analysis to findings in math at both the elementary and secondary levels and found that the effects of peer tutoring were positive. In addition she found that tutoring effects were stronger than those found with individual learning programs or computer-based instruction. A review by Cohen, Kulik, and Kulik (1982) stated that Hartley's (1977) work advanced the knowledge of tutoring, though the scope of her project was somewhat limited. They pointed out that Hartley's (1977) analysis covered only mathematics teaching and thus could not determine whether these effects would be evident in other content areas. In addition she only studied achievement effects and did not determine whether tutoring had any effects on other instructional outcomes such as attitudes toward school and school subjects or self-concept.

Cohen et al. (1982) also noted methodological weaknesses in Hartley's study. They reported that she aggregated effects on both tutors and tutees and that her analysis was based more on the findings rather than actual studies, which in turn made it difficult to determine statistical error. Another methodological weakness was that her pool of studies included some which lacked adequate methodological considerations, such as a control group. Nonetheless, Hartley's (1977) work helped to extend the scope of reviews.

Cohen et al. (1982) conducted their own meta-analysis examining student achievement, attitudes toward the subject matter, and student self-concept. They defined 15 variables to describe the studies: four outlining types of tutoring programs, three concerning experimental design variables, six describing features of the course setting, and two describing the features of the publication.

They found that academic achievement of tutees was reported in the majority of the studies analyzed. They also indicated that tutored students often performed better than students in conventional classes. Of great import to student learning were the author's findings that certain program features produced stronger effects. If the programs were structured or had shorter durations, the effects on student learning were larger. Tutoring effects also were stronger when the skills taught and tested were of lower difficulty, when math rather than reading was the content, when tests of achievement rather than reading assessed the content, and when tests of achievement were locally developed (Cohen, Kulik, & Kulik, 1982).

In evaluating the effects on the student tutors, the authors found that in about half of the studies achievement effects on tutors were reported. Tutors performed better than did their control counterparts on tests of the subject matter being taught.

In addition to the many studies conducted with students in the regular education classroom, numerous investigations exist encompassing students with various designations of disability (learning disability, behavior disorders, intellectual deficiency). And reviews have been conducted to determine the overall effectiveness of peer tutoring programs incorporating the child with a disability. For example, Cook, Scruggs, Mastropieri, and Casto (1986) focused on studies involving students with learning disabilities, intellectual handicaps, and behavior disorders, as defined by Public Law 94-142. Their emphasis was on the student with a disability serving as tutor. However, social and academic benefits for both tutors and tutees were quantitatively evaluated using means to judge the studies.

In their article, Cook et al. (1986) did not list the studies they reviewed; however, the results of their meta-analysis indicated that performance levels for tutors and tutees increased over one-half of a standard deviation above the control groups. They also reported that greater gains were evident when objective nonstandardized instruments rather than norm-referenced tests were used and the length of the intervention did not affect the effect size.

Cook et al. (1986) concluded that tutoring is a feasible and potentially powerful technique for students receiving services under labels of learning disabilities, behavior disorders, and intellectual handicaps. They found several examples of these students functioning with success in the role of tutor. Areas cited by these reviewers as needing continued investigation included the examination of social and emotional benefits, specific components of tutoring, and the relation between tutor gains and the content taught.

Research on Affective Outcomes

The social benefits that might accompany the pairing of students in a teaching situation also have been studied. Of importance have been the studies exploring the change in social acceptance resulting from the tutoring process. Studies by Custer and Osguthorpe (1983) and Osguthorpe, Eiserman, and Shisler (1985) indicated that tutors with disabilities experienced substantially more positive social interactions with their nondisabled peers as a result of the tutoring intervention. The multiyear study conducted by Osguthorpe et al (1985) noted a lasting effect in social acceptance: Students with disabilities who tutored interacted more with regular class peers than those who did not tutor. This suggests that personal/social progress could be enhanced by scheduling time for peer tutoring interventions.

Social benefits have been more systematically investigated when determining benefits for the student with a behavior disorder than for the one with a learning disability. Csapo (1976) found that tutors assigned a behavior disorders' label showed an increase in social functioning by expressing more self-confidence and more responsibility. Csapo (1976) further reported that the tutors' number of positive remarks increased, they returned home earlier at night, and the number of adjudicated delinquencies decreased. In a study of disruptive adolescents, Lane, Pollack, and Sher (1972) found that when these students became tutors, their disruptive behavior decreased and they expressed less anger. These tutors also reported increased self-confidence and responsibility.

Maher (1982) found that tutors with behavior disorders demonstrated improved behavior more often than did tutees with behavior disorders and than students with behavior disorders who were receiving counseling. Maher (1982) found substantial decreases in disciplinary referrals and rates of absenteeism among the tutors with behavior disorders. Additionally, Top (1984) reported that tutors with a behavior disorder showed an improvement in their perceptions of their own abilities. Osguthorpe et al. (1985) also reported that tutors demonstrated greater improvements in social acceptance than did controls. The findings of Maher (1982), Top (1984), and Osguthorpe (1985) are strengthened because of the use of control groups by these researchers.

Although many studies indicate positive findings related to social acceptance and benefits, others reveal inconsistent or negative findings. Franca (1983), using a tutorial model with adolescents with behavior disorders serving as tutors and tutees, found few and inconsistent changes in self-concept and teacher perceptions of behavior. However, tutors and tutees demonstrated improved attitudes toward math and increased social interaction.

A more theoretical review of the social benefits attained by peer tutoring was conducted by Leyser and Gottlieb (1981). The authors listed different types of approaches that have been used to improve the social status of students with disabilities: sociometric grouping, cooperation, student active participation and involvement, rewarding social interaction, coaching, and peer tutoring. They reported that social status may be improved by decreasing inappropriate behaviors. The authors contend that by pairing a shy or withdrawn child with a popular student, the shy student will begin to model the outgoing child's behavior. Additionally, Leyser and Gottlieb (1981) stated that given the role of teacher, the tutor has an opportunity to employ more socially appropriate behavior.

Siperstein, Bak, and Gottlieb (1977) conducted a study on the effects of group discussion on children's attitudes toward peers with disabilities. They found a negative shift in attitudes toward a child with a disability regardless of grouping (friends or nonfriends). The authors suggested that children's interactions in groups may be an important factor to consider in determining the extent to which a child with a disability is asked to participate. In 1980, Siperstein and Bak conducted a study to improve peer attitudes toward blind peers. They reported that although the children "felt better" toward their peers with visual impairments, they actually engaged less in activities with the peers. In general, the authors reported more negative outcomes regarding social acceptance when students were paired with students with visual impairments.

In a study by Ballard, Gottlieb, Corman, and Kaufman (1977) positive results were noted in social acceptance of students with educable mental handicaps when paired with nonhandicapped students. However, social acceptance was not measured by direct observation.

Shisler, Osguthorpe, and Eiserman (1987) investigated the effects of reverse-role tutoring on the social acceptance of students with behavior disorders, based on the idea of mainstreaming students who were diagnosed with behavior disorders. The authors introduced a tutoring intervention strategy placing the student with behavior disorders in a higher status role (tutor) and paired these students with peers in regular education classes. The authors measured the change in attitudes by the regular education students toward the group of students with behavior disorders with whom they worked. They also measured whether hypothesized attitude changes were generalized to a second group of students with behavior disorders in the same school.

Students with behavior disorders were trained in basic sign language vocabulary for about 6 weeks. The tutoring sessions lasted 15 to 20 minutes and were conducted in each of the two classes four times weekly. The tutors were taught to be effective tutors. Tutoring sessions lasted 7 school weeks.

Results of this study revealed that reverse-role tutoring produced significant changes in the tutees' attitudes toward their tutors with behavior disorders. However, the study did not indicate that tutee acceptance of their tutors was generalized to another class of students with behavior disorders. In addition no significant changes were noted for the control group. The tutees' responses to their tutors fluctuated and Shisler et al. (1987) contend that research is still necessary to determine if classmates will indirectly accept students with behavior disorders as a result of tutoring.

In a more recent study (García-Vázquez & Ehly, 1992), the authors of this chapter investigated the effects of a structured peer tutoring program on the social acceptance of students in regular education classes. Students perceived as not socially accepted were paired with students rated as well liked by their peers. Three conditions were tested: Students perceived as not socially accepted were either (a) tutors, (b) tutees, or (c) part of a control group. The results were significant for type of student, distinguishing between students who were rated as liked and those who were not. Significance was obtained for experimental groups on a time variable, suggesting that regardless of role, changes in acceptance would be obtained over time. Mean analysis, however, indicated that students who were rated as disliked and served as tutors were rated higher on the "like" variable following the tutoring intervention.

As important as the studies involving peer tutoring effects on social and academic benefits are another area requiring more research is investigation of the interactions that occur in the peer tutoring process. Fogarty and Wang (1982), for example, conducted a study to obtain more descriptive information about the interactions within the peer tutoring dyads. The study examined the process from an analysis of the verbal interactions and documentation of academic and attitudinal progress. Of interest were the effects of peer tutoring on the give-and-take exchange between tutors and tutees as well as the motivational force that yields positive academic effects and attitudinal progress.

Another study by this chapter's authors and an associate (García-Vázquez, Ehly, & Vázquez, 1993) examined tutee and tutor verbal interactions to determine the extent to which peer tutoring affects the perceptions of students when the tutor was either accepted or not accepted socially by peers. The results indicated that students initially disliked were more liked at the conclusion of the tutoring intervention when serving as tutors. The findings also indicated that the tutors who were initially liked provided more positive feedback, suggesting that training tutors to provide adequate verbal comments may influence the outcome of tutoring.

Implications for Practice

From the articles reviewed, evidence has accumulated to suggest that both tutors and tutees benefit from the tutoring experience. More specific and definite results have been found in terms of academic gains. Tutors and tutees have shown increases in achievement in subjects such as math, spelling, and reading. Positive academic results in general subject concepts are noted in several studies while in others more specific academic skills were evaluated. Nonetheless, peer tutoring has been proven to work when academic gains are attempted. Studies of social benefits, on the other hand, have produced inconclusive data at best. While some studies note positive findings in social acceptance, others note negative results. Further, in several studies social gains have not been systematically evaluated.

Tutors and tutees receive specific academic gains when tutored by special education students, regardless of content areas (e.g., math, spelling, or reading) and regardless of disability. Students with learning disabilities, mental handicaps, or behavior disorders can serve as tutors of other disabled and nondisabled individuals.

Investigations involving students with behavior disorders have focused more on the social benefits of tutoring than have investigations of students with other disability labels. However, lack of stringent research methodology, control groups, and differences in intervention programs have resulted in inconsistent findings. In addition, the studies have focused on students with a diagnosed disability and not much attention has been given to students who demonstrate mild behavior problems or no diagnosed disability. Further, the tutoring with behavior disordered students has been conducted primarily in self-contained classes and not in regular education settings.

The overall implications of the research on practice relate to the procedures, type of program, length of program, and subject matter. Even though the research on the effectiveness of tutoring varies in quality, overwhelmingly the results have been positive with the major variation being on the degree of program effectiveness. In deciding to develop and implement a peer tutoring program, individuals can feel confident that when academic gains are the goal, a tutoring program can facilitate this objective. In terms of affective goals, continued research is needed and how the program to influence social variables is set up will be important. One critical finding is that students having an opportunity to serve in a tutor role may help to empower student participants.

The more specific implications related to program structure such as type of program, tutor training, length of program, and other factors, are addressed in the next section.

Implementing a Peer Tutoring Program

Once a decision to implement a tutoring program has been reached, the next step is to plan the best possible program. Seven areas to consider are

- Specifying goals and objectives.
- Developing a strategy for the assessment of outcomes.
- Specifying materials and procedures.
- Training tutors for their role.
- Developing a monitoring procedure.
- Conducting a small-scale program before implementing a large-scale effort.
- Considering time and cost factors. (Ehly & Larsen, 1980)

Tutoring programs that have succeeded involved one or more of the seven elements. Often, the chances for success are increased when all these elements are implemented into a peer tutoring program.

The best time to specify goals is before the development of any other component of the program. Defining goals involves deciding what will be gained from a tutoring program. The goals can be simple or complex and fulfill a variety of purposes. Perhaps the program could free the teachers' in-class time to develop instructional materials. A teacher may want to have structured time set aside for one-to-one instruction and review with students who may require additional assistance. Tutoring sessions also can be used to reinforce short-range objectives or to increase the skills via tutoring in conjunction with classroom instruction (Ehly & Larsen, 1980).

The language of goal statements is general, providing a focus for the set-up of the tutoring project. While a goal statement could be similar across different projects (e.g., increase academic achievement), implementation of the program can be in divergent ways. Nonetheless, goal statements serve as the general structure within which specific objectives can be implemented.

Developing objectives for tutoring programs is a process that involves translating the intent of goals into observable, behavioral statements. To add an evaluation component, frequency of numerical total statements can be added to the objectives to determine the extent to which the goals have been met (Ehly & Larsen, 1980).

Developing specific objectives to reflect the tutoring goals leads directly to the need for a statement of evaluation standards. Specifying competency standards for the students during tutoring provides both tutors and tutees goals to achieve in their partnership.

The extent to which strategies for assessment are developed varies widely. Yet setting evaluation standards prior to tutoring is as important as setting goals for the tutors and learners. Learners could be tested only on the content of each session, providing a consistent flow of information on the success of individual tutoring sessions (Ehly & Larsen, 1980). However, daily student evaluations are time consuming and consideration must be given to the degree of energy to achieve success with the tutoring program. The time spent necessarily will vary with the goals set for the program. If the goal is to increase the degree of interaction among students, detailed daily evaluations may not be critical. However, if the goal is to document learning gains, a more detailed data-based assessment, like a paper/pencil test, may be helpful.

Finally, goals for the tutor are also important to consider. While tutoring programs generally are implemented with the student learner in mind, the research is overwhelmingly positive on the benefits of tutoring for the tutor. Strategies for evaluating tutor progress are warranted. Again, depending on goals for the tutor's participation, the procedures for assessment will vary. When the results indicate that both partners benefit from the tutoring, a stronger case is made for tutorials.

As decisions are made about the program, such as goals, objectives, and evaluation standards and procedures, deciding on which materials and procedures to use will flow naturally (Ehly & Larsen, 1980). Materials can reflect the intent of the program as well as provide the content for the tutoring sessions. Just as with every other step in implementing a tutoring program, making decisions about materials prior to the start of the program will facilitate the process of implementation. Time can be spent early in the process searching for ready-made activities or developing materials so that the tutoring program will flow effortlessly.

Materials similar to those used in regular classroom activities are easily accepted by tutees and do not require much training of the tutors. Previous research indicates that students learn best when the tutoring program supplements the regular classroom instruction (Ehly & Larsen, 1980).

Procedures for presenting materials will depend on the type of tutoring program developed. For example, programs in math and reading will differ on disciplinary lines defined by the subject areas (Ehly & Larsen, 1980). However, the goal in procedure-development is to select the simplest, most direct approach for presentation of information by the tutor.

Another important consideration is tutor training. While the extent of tutor training may vary, research underscores the importance of this element to the success of the program (García-Vázquez & Ehly, 1992). Instructions can be as simple as stating expectations or as complex as providing several sessions of training. In implementing tutor training, four elements need to be considered: students, scheduling, space, and resources (Ehly & Larsen, 1980).

Student academic, social, and other information can be useful in making a decision on whether the student will succeed as a tutor, given the tutoring program goals. Tutor training sessions will alert students to the demands that will be placed on their time and effort. The sessions can provide an indication of the student's readiness to assume the tutor role. When tutoring involves students with disabilities, it is important to plan training sessions that will maximize the experimental students' ability to participate successfully in the tutoring program (Ehly & Larsen, 1980). All students with motivation and the ability to work with a partner have something to contribute to tutoring programs. The key is determining in which way and with what type of program the student will be most successful.

Scheduling tutorials raises crucial considerations given the limited opportunities that teachers have to devote to programs outside of their regularly scheduled activities. Setting up a tutoring program may result in borrowing from planning time in order to develop and implement a program. Of course the goals and the complexity of the program will determine how much time will be required, with more complex tutorials demanding more time to prepare and implement. However, scheduling demands can be minimized by contributions from supportive colleagues and administrators.

In training tutors, sessions optimally will be conducted in an area that will accommodate all of the tutors in the program. In cases of limited space, however, a few tutors at a time could be trained, making sure that the information presented is consistent across sessions. In any case, it is important that enough room is allowed for students to handle materials and role play skills. Often training can be completed in the students' classroom.

Training can include giving the students an opportunity to use the materials prior to commencing the tutorials. Tutors can locate and become familiar with the materials they will use. However, it is the school psychologist's or the teacher's responsibility to make sure the materials needed are easily available (Ehly & Larsen, 1980). Other teachers, staff, former tutors, and parents can serve as resources for the tutors. It is important to point out these people, discuss their roles, and provide the students an opportunity to talk with them.

The bottom line with training tutors is that the success of the program often is determined by the effectiveness of training. Just as important is the teacher's success in monitoring tutors while teaching tutees. Ongoing monitoring provides information on progress, so that the tutors can be praised, retrained, or reminded of tutoring components.

Training sessions can be structured using the principles developed by Deterline (1970). Deterline (1970) points out that tutors can learn to (a) put the learning partner at ease, helping to set the tone of the tutorials; (b) clarify learning expectations, showing the tutee how to verify answers and direct the learner on response procedures; and (c) provide feedback contingent on responses as well as help the tutee verify responses. As demonstrated in previous research, training tutors to provide verbal praise (García-Vázquez & Ehly, 1992) and avoid punishment is highly desirable. When the structure of tutorials calls for providing tangible rewards when appropriate, it becomes necessary for the tutor to know when and how to do so. Finally, Deterline (1970) suggests that tutors need to evaluate all elements of mastery on designated problems.

Monitoring students in the tutoring sessions will indicate whether students are following the designated sequence and using the materials appropriately. Interventions can be made early in the program if students are having difficulty with the process. When students understand the expectations, they will work cooperatively and freely. In addition, monitoring will aid in determining which students need assistance and reinforcing tutors and tutees who demonstrate positive behaviors.

Monitoring the tutee's progress through observations of behavior during tutoring, results on pencil/paper tasks, and attitude toward the process are also critical aspects contributing to the success of the program. This monitoring of the tutee can become a database on tutorial processes so that effects of tutoring can be more clearly established. By coupling curriculum-based measurement with peer tutoring

(Phillips et al., 1993), program effectiveness and student learning can be monitored in a structured, databased manner. Therefore, monitoring includes examining the progress of the program, the tutor, and the tutee.

Other information that can assist in the development and implementation of tutoring programs includes pilot projects, time and cost considerations, and sources of additional assistance. Often pilot projects will provide knowledge of how a program will work on a smaller scale, and, as a step in a larger program, can be used to refine materials, strategies, procedures, and structure (Ehly & Larsen, 1980).

Developing and implementing a tutoring program can take a lot of time, energy, and money. It becomes important to objectively note what has and has not worked with tutorials to prepare for future endeavors. Teachers can work with administrators to make efficient use of time and to seek financial support. The key is to facilitate the venture without adding on unnecessary hours of labor to an already exhausted profession. In addition, tutoring projects can be financed by schools so that the teacher does not have to use personal funds (Ehly & Larsen, 1980).

Anyone interested in developing and implementing a program can turn to others for assistance, the obvious individuals being other teachers and administrators. Many times if a group of teachers is interested in a project, assistance from principals can be obtained. Support from parents also can be sought. Many parents appreciate feedback on their children's learning experiences and may volunteer to help develop or implement the program. Assistance from parent, teacher, and student organizations can be pursued. Student councils can help put materials together, fill out forms, or perform other regular but time-consuming tasks. Students, in addition to being part of the program, can serve as monitors, pass out assignments, and perform other duties (Ehly & Larsen, 1980).

Other resources can be found in the community. Many community groups have strong interests in education and may provide financial support, materials, and volunteer help. If the school is located near a university, that faculty can be a valuable resource. Many are abreast of the current research, can serve as guides, and have access to students who may want to volunteer to work with a program. Many universities have outreach and precollegiate programs whose intent is to connect with schools.

Tutoring programs work. How they will work in specific situations will depend on the preparation conducted prior to commencing the program. The ideas just described serve as guidelines for developing and implementing a tutorial program. A person's theoretical orientation will determine which specific strategies and activities will be selected for the program.

SUMMARY

School psychologists, as consultants to educators and liaisons to the school for an array of service options, are in an ideal position to introduce peer tutoring activities. Examples exist of a wide variety of individual and group tutorials. At the most basic level, school psychologists can serve as a resource to teachers, administrators, and parents interested in adopting peer tutoring interventions.

At the level of problem solver within the schools, psychologists can add peer tutoring to their list of academic intervention options that can be pilot tested with individual students or groups of children. Peer tutoring also may be implemented in community agencies providing after-school or alternative education services and in the home with sibling involvement.

The school psychologist as consultant and resource for evaluation and research can fulfill additional roles in guiding and assisting educators to assess the benefits of peer tutoring. The training of most school psychologists prepares them for these responsibilities. The problem-solver approach to service is entirely consistent with the available evidence on the implementation and evaluation of tutoring.

Peer tutoring is not new; it has been implemented in thousands of classrooms. When educators and parents become familiar with peer tutoring and its benefits, it can become an attractive intervention option. If the educator or psychologist has not implemented any previous peer tutoring programs, the amount of time and effort needed to achieve the desired outcomes from tutorials add to start-up considerations. School psychologists can serve as catalysts in planning, implementing, and evaluating activities by educators and can provide the support necessary to ensure positive learning outcomes for all students.

Best Practices in Assisting with Promotion and Retention Decisions

Mary Ann Rafoth
Indiana University of Pennsylvania

Karen Carey
University of California at Fresno

OVERVIEW

We often associate the month of May with a sense of relief that winter is over and that a school year has ended successfully. But in classrooms across the country May is a time when some students and parents receive the unsettling news that a retention is being considered. Teachers grapple with the difficult decision that can affect a child's future so dramatically. Consider these scenarios: (a) A preschool teacher tells the parents of a 4-year-old boy with a birthday just before the school cutoff date that they may want to have him spend another year in preschool before facing the demands of public kindergarten; (b) It is recommended to parents of a first grader that their daughter be retained in first grade — because she's slow picking up reading and appears younger than her classmates; (c) A teacher recommends that a boy in fifth grade repeat the year because, while he appears bright and capable of doing the work, he has done very little in class and has handed in virtually no homework assignments; (d) A group of eighth-grade teachers draw up a list of students they feel have not mastered the academic skills necessary to proceed to high school. Many of the students have already repeated one year in school; most are boys from lower socioeconomic classes who have been placed in the lower tracks since early in elementary school; (e) A high school sophomore with frequent absences from school is forced to repeat 10th grade because she has failed to accumulate sufficient credits to enter the 11th grade. Every year, approximately 2.3 million U.S. students are held back in school, many under circumstances similar to those described above. Frequently, school psychologists are involved in making retention decisions. The efficacy of retention, while it is a common educational practice, is not supported by research literature. For the most part, retention is of questionable educational benefit and may have negative effects on achievement, self-concept, and school dropout rates. Nevertheless, teachers continue to believe in its efficacy. Tomchin and Impara (1992) found that surveyed teachers saw retention as a positive practice that acts to lessen daily school failure and to motivate students to work harder.

This chapter provides the school psychologist with a brief review of the research on student retention as well as discussion of the issues involved when schools make retention decisions. The concluding section will address the role school psychologists may play in making retention decisions and will suggest alternatives to retention that may better meet the needs of students experiencing failure at school. Of the many professionals involved either in developing districtwide retention policies, or in making retention decisions about individual students, the school psychologist is uniquely qualified to act as a consultant in generating alternatives. School psychologists should help to evaluate the reasons for school failure, plan appropriate instructional programs for the following year whether or not the child is retained, and act as consultants both to parents faced with retention decisions and to their school districts in developing programs that are viable alternatives. Best practices regarding nonpromotion center on a thorough understanding of the research and careful consideration of the needs of the individual student.

BASIC CONSIDERATIONS

Retention or nonpromotion is the practice of requiring a child to repeat a particular grade or requiring a child or appropriate chronological age to delay entry to kindergarten or first grade. With the introduction of graded schools in the nineteenth century, retention emerged as a response to the problem of students unprepared for the academic demands of the next grade. While concern about possible negative effects of retention has been expressed since the 1930s, the practice continues to be widespread. In fact, retention remains a common educational practice although little research exists to validate its effectiveness (Holmes, & Matthews, 1984; Medway &

Rose, 1986; Shepard & Smith, 1989). While these reviewers and others (e.g., Jackson, 1975) have concluded that much of the research is flawed or of poor quality, the use of statistical techniques such as meta-analysis and causal modeling can help overcome the weaknesses of individual studies and help establish more definitive relationships between retention and later achievement and social growth.

Kindergarten and Elementary Level

Children are often recommended for retention at the kindergarten level because they have failed to acquire basic readiness skills. Sometimes these determinations are made because of poor performance on a readiness test administered before entry into kindergarten or at the end of the year. Failure to display skills in the classroom that is coupled with low achievement scores is often the reason a child is suggested as a candidate for retention after completing a year of kindergarten. Some children enter kindergarten with little exposure to academics, the school routine, or prerequisite skills such as letter and number recognition, which are typically taught in most preschools. Children from home backgrounds in which such exposure is limited may find themselves candidates for delayed entry into kindergarten or retention.

Delayed entry or retention at the kindergarten level also occurs because some children are judged to be "developmentally immature." These children seem to be slightly delayed in social, motor, and/or readiness skills and in need of a year to grow or mature neurologically and thereby catch up with their peers. Likewise, children who are physically small or relatively young compared with their peers (because of cutoff dates for school entry) are often candidates for delayed entry or retention. Many parents and teachers believe that the extra year will allow the child to compete more effectively with peers the following year.

While late-birthdate children who are retained or held out of school for a year initially may do better than those enrolled in first grade at the prescribed age, longitudinal studies show that initial achievement gains do not hold up over time. For instance, Miller and Norris (1967) divided first graders into three groups based on age at school entrance. They found significant differences between young, middle, and old first graders on three of six readiness measures. At the end of 4 years, however, the average achievement of the young group did not differ significantly from the average achievement of the middle group. Similarly, some research suggests that retention in kindergarten or first grade may be associated with poorer academic and social functioning throughout the elementary grades (Armistead et al., 1992). In a similar study, Hauck and Finch (1993) noted that their results were consistent with earlier research: differences in achievement related to age exist to some extent in elementary school but tend to diminish and even disappear by middle school. Additionally, May, Brogan, and Knoll (1993) found no relationship between children's birthdates and later classification as handicapped. Profiles of children who are retained in kindergarten indicate that they have multiple deficits and needs, making it unlikely that simple exposure to the same curriculum would be an effective intervention (Mantzicopoulos, Morrison, Hinshaw, & Carte, 1989).

Many schools have adopted transitional or developmental programs for children "not ready for first grade." However, these programs appear to be no more effective than retention (Ferguson, 1991; Gredler, 1992; Mathews, 1977; Talmadge, 1981). Zinski (1983) found no significant differences between children who attended a transitional program between kindergarten and first grade at the end of first grade and children who repeated first grade. Gredler (1983) reviewed seven studies that investigated the effects of transition room placement and concluded that "research indicates that transition room children either do not perform as well or are at most equal in achievement levels to transition room-eligible children placed in regular classrooms."

Perhaps the most comprehensive review of the effects of retention was conducted by Holmes and Matthews (1984). They conducted a meta-analysis of 44 studies, calculating 575 effect sizes to determine the effects of retention on a variety of factors, such as achievement, personal adjustment, self-concept, and so on. The authors defined effect size as "the difference between the mean of the retained group and the mean of the promoted group, divided by the standard deviation of the promoted group." Meta-analysis has become a popular way to aggregate a large number of studies that investigate a common research question.

All the studies selected by Holmes and Matthews compared a group of retained students with a group of promoted students. Thirty-three of the studies investigated achievement effects. These studies yielded an overall effect size of −.37, indicating that retained students scored significantly lower than promoted students on achievement measures. While teachers believe that retention in the grades kindergarten through third grade is not harmful (Tomchin & Impara, 1992), when Holmes and Matthews analyzed the data by the grade level in which the retention took place (Grades 1–6), they again found negative effects at all grade levels. This calls into question the commonly held belief that the earlier a student is retained the greater the likelihood that retention will produce positive effects.

While proponents of retention maintain that promoting children when they are not ready can have a harmful effect on personal adjustment, the bulk of the research does not support this contention. In addition to achievement effects, Holmes and Matthews (1984) also calculated effect sizes on personal adjustment measures taken from 21 studies. They found negative effects for social adjustment, emotional adjustment, and behavior, as well as self-concept, as did another study on the long-range effects of retention (Armistead et al., 1992). Many studies have found that students' attitudes toward retention are negative. Byrnes and Yamamoto (1984) found that children who are retained recognize the change as failure and feel ashamed. In their study children rated retention behind only blindness and a parent's death as most stressful experiences. Smith and Shepard (1989) reported that clinical interviews with retained students indicate that these students saw their retention as "flunking" and as punishment. In this same study, parents of retained kindergartners reported that their children experienced teasing and adjustment problems because of their nonpromotion. Johnson (1981) argued that children who have failed in school show characteristics of learned helplessness. The students in his study were likely to attribute failure to themselves and to deny responsibility for success.

Secondary Level

At the secondary level (i.e., middle school, junior high school, and high school) students are most often retained for two reasons: (a) a lack of sufficient credits to be promoted to the next grade level or to graduate from high school, or (b) a failure to pass mandated minimum competency exams. Through the sixth grade, retention rates tend to decrease with each year. However, when students reach the seventh grade retention rates rise and continue to increase in subsequent years (Medway & Rose, 1986; Rafoth & Carey, 1991). Generally the increase in retention rates is due to students' inability to meet the school district's standards for promotion or to obtain sufficient credits to graduate from high school. Often these students have received failing grades, have demonstrated higher absenteeism than their promoted peers, have been retained in earlier grades, and have experienced higher rates of discipline incidents (e.g., suspensions) (Fleming & Zafirau, 1982). Alternative education is often not provided to these students, and for many life outside of school becomes more important.

Perhaps prompted by employers' doubts about the meaning of a high school diploma and society's current attitudes toward perceived deficiencies in the U.S. educational system, many states now require students to pass minimal competency exams in order to receive a high school diploma. However, many students are unable to pass these tests because of poor reading skills and/or academic performance, and retention becomes the "intervention" of choice. Once retained, remediation often does not occur during the student's retained year, and the student makes little, if any, gains in academic performance (Purkerson & Whitfield, 1981). Many school policymakers believe that retaining students unable to pass minimum competency tests will motivate those students to improve skills and complete the necessary requirements for graduation. However, students are often not motivated by retention and once they have experienced retention, they often equate the circumstance with failure, view themselves as failures, and thus drop out of school (Thompson, 1980). It appears that setting higher standards and administering competency testing do not improve the academic performance of students most at risk for school failure. Instead, these actions may result in an increase in the number of students who are retained and drop out of school (Hamilton, 1986).

Research on retention at the secondary level has generally examined the relationships between grade retention and attendance, suspension, and self-concept, with an emphasis on the correlation between retention and dropout rates (Rumberger, 1987; Wehlage & Rutter, 1986). Retention rates at the high school level have been found to be related to attendance and suspension rates (Fleming & Zafirau, 1982). Generally, students who are failing do not attend school on a regular basis. In addition, students who have been retained prior to the secondary level are less likely to attend school on a regular basis in junior and senior high school. Additionally, regardless of the grade in which retention occurs, secondary students who have been retained often exhibit low self-esteem. In a follow-up study of high school students with a history of grade retention, Hagborg, Masella, Palladino, and Shepardson (1991) found that retained students were lower on a number of variables, including achievement, intelligence, and grades, and were more often absent from school and scored lower on a measure of self-esteem than did nonretained peers. They did note that students retained later in their educational careers displayed even lower grades, less positive school attitudes, more discipline problems, lower self-control, and a more externalized locus of control. General conclusions drawn from many studies suggest that retention correlates negatively with students' self-concept, peer acceptance, and personal adjustment.

The majority of the research on retention at the secondary level has focused on the relationship between retention and dropping out of school. This relationship can be explained by two competing hypotheses: (a) Repeating a grade may increase the risk of dropping out, or (b) Poor achievement may account for both retention and dropping out.

In many early studies undertaken to analyze the relationship between retention and dropping out of school, the achievement variable was not controlled. However, in a number of more recent studies (e.g., Grissom & Shepard, 1989) the achievement variable was adjusted in order to focus only on the relationship between retention and dropping out. It has been found that the dropout rate of overage students (retainees) is appreciably higher than the dropout rate of regularly promoted students when reading achievement scores are equivalent for the two groups. Even in high-socioeconomic school districts, where students are less likely to leave school, a significant increase in dropout rates has been found for retained students.

Do Some Children Benefit from Retention?

Sandoval and Hughes (1981) found that the children who made academic and social gains after repeating first grade had not experienced serious academic deficits in the year prior to retention, had strong self-esteem and social skills, and had shown signs of difficulty in school because of lack of exposure to academic materials (e.g., because of high absenteeism, illness, or frequent family moves) rather than low ability. In a 5-year follow-up, Sandoval (1987) found that these same factors predicted success in the upper grades. However, Smith and Shepard (1989) make two points about this study: (a) The fact that relatively high achievement and high self-concept prior to retention correlated with positive outcomes implies that the most successful retainees are those who need it the least; also (b) even the most successful retainees are no better than promoted controls on a variety of outcome measures at the end of first grade.

At times, retention is employed in an attempt to postpone or supplant special education. However, there is little evidence to support the use of retention in this way (Carstens, 1985; Chandler, 1984; Lieberman, 1980). Cross (1984) found that the most important factors governing a teacher's decision to recommend retention were failure to complete a primer designated by the school district; general immaturity; and anticipated resistance from the child's parents. Cross found that there were no differences in the reading achievement test scores of the children recommended and those not recommended for retention, and none of these factors have been shown to be useful predictors of successful retention.

Some researchers have believed it possible to predict which students benefit from retention and have encouraged schools to develop decision-making procedures to aid in selecting likely candidates (Lieberman, 1980; Light, 1977). Others have rejected such a process. Smith and Shepard (1987) conclude from their own research and their review of the literature, "Although some small percentage of those retained may be helped, the evidence indicates that educators are simply unable to predict accurately which individuals these will be."

BEST PRACTICES

Alternatives to Retention

School psychologists' involvement with retention practices can occur on several levels. It can range all the way from participating in making retention decisions about individual students to influencing school or districtwide retention policies, to lobbying for change on a state level through the collective efforts of a state school psychology association. An important effort at each of these levels should be to promote the use of alternatives to retention that will be more effective in remediating the skill deficits of students.

Individual Retention Decisions

School psychologists can be important participants when decisions are made about retaining students in their schools. They should help evaluate the reasons for school failure by looking at the children's school and developmental histories, the effectiveness of the instruction they have received, and the remediation strategies or programs available to them. The school psychologist should help plan an appropriate instructional program for the following year, whether or not the student is retained, and should act as a consultant both to parents and to school personnel to help them make retention decisions.

Two case discussions may help illustrate the part the school psychologist can play in making retention decisions. In the first case, a child whose first-grade teacher recommended retention was referred by her parents to the school psychologist for testing to rule out the possibility of a learning disability. The teacher reported that the student was having difficulty getting beyond the primer level in reading, her attention span seemed somewhat short, she had some trouble completing work independently, and she also seemed to be exhibiting some "immature behaviors" such as fidgeting in her seat and putting her fingers in her mouth. The child, an attractive, petite girl, was assessed as having average intelligence with achievement commensurate with her ability. The school psychologist met with the child's teacher and parents. She reviewed the test results and then led a discussion about retention. She summarized the research on retention, stressing that there is little evidence that it helps over the long term. She indicated that initially students who are retained in first grade show some improvement over similar students who are not retained but that these gains tend to disappear by third grade. She noted that the child's teacher was trying to make the best decision for the child as she could precisely because she was worried about the child's progress in the coming year, thereby lending support to the teacher without necessarily espousing her recommendation.

The school psychologist reported that while some children do seem to benefit from retention, at present educators lack the ability to predict reliably just which children will benefit. Therefore, she stressed to the child's parents that it would be important that they feel comfortable with whatever decision they made, since undoubtedly the child would sense her parents' comfort or discomfort with the decision. This statement was emphatically echoed by the child's teacher. The decision was left in the parents' hands. The mother later reported to the school psychologist that she had decided not to have her daughter retained. She indicated that as a child she had matured at a young age and she was worried that the same would happen to her daughter. She was concerned about the effect of early maturation, particularly if her daughter were already a year older than most of her classmates. While this parent decided to have her child continue on to second grade, she wanted to be sure her child would be able to get supplemental reading services and that her teachers would continue to monitor her progress in reading.

In a second example, a school psychologist became involved in the case of a kindergartner being considered for retention. In this case, the school psychologist led a team discussion, first questioning why retention was being considered. The classroom teacher pointed out that the child had spent most of the year in kindergarten with an undetected hearing loss and hence it was unclear how much the student had been able to benefit from instruction. The school psychologist then referred to the section of the NASP Position Statement on Student Retention (see Appendix), which specifies when retention is less likely to be harmful. She went down the list: Does this student lack serious academic skills deficits? Does the student have positive self-esteem and good social skills? Has the student had difficulty in school because of lack of access to instruction? The group decided that the answer to these questions was yes, and hence this youngster might benefit from retention.

Most parents and educators are unaware of the research on retention. The school psychologist should be willing to share this research to help schools and parents make informed decisions. This information should not be imparted dogmatically or in a way that impairs working relationships with colleagues or parents. In some cases, this may mean recognizing that schools will make decisions to retain children when the school psychologist feels it is not in the best interest of those children. Especially in these cases, it will be important for the school psychologist to participate in developing a specific plan of action by which the student's skills deficits can be remediated. School psychologists are encouraged to gather follow-up data on children who have been retained and children of comparable achievement levels who are not retained, to help their school districts better understand the outcomes of retention decisions.

School District/System Level

School psychologists' participation at a school district or system level can take many forms. As within their own schools, they can publicize the research on retention to help guide the development of informed policies. They can also serve an evaluative role, using districtwide data to assess the outcomes of retention decisions. And they can monitor the progress of students to ensure that problems are identified and addressed early, before retention becomes a consideration. School psychologists can also promote the development of effective alternatives to retention at all grade levels, from preschool through high school. These can include both developing programmatic interventions that address the needs of failing students and expanding the capabilities of classroom teachers to meet the needs of students at different skill levels.

Programmatic interventions may include developing screening programs to identify children at risk for school failure and to ensure early access to programs already available in the school or community, such as Head Start, Chapter I services, and remedial programs. It may also include developing intervention programs such as after-school tutoring or summer school courses. At the secondary level, school psychologists should encourage the development of reentry programs for dropouts and alternative education programs, such as ones that combine teaching skills with job training. Successful programs at the high school level often have two characteristics: (a) one or more individuals who develop relationships with students individually and monitor their progress carefully; and (b) some mechanism to allow students who have failed courses and lost credits to regain these credits in quicker than normal time, allowing for graduation at the expected time.

One program that exemplifies this approach is Project Stay, developed in Charleston, Illinois. At-risk students are identified by school counselors and teachers and invited to join the program. The students must make a commitment to the program and then be "voted in" by current student members. The Project Stay coordinator develops a strong relationship with each student, giving them wake-up calls at home, checking homework, and meeting them at the school door. Project Stay students complete some coursework in the Stay classroom in small classes and at their own pace. The classroom is equipped with living room furniture and is generally appealing to students. Students who complete failed coursework in the Stay classroom may cover several courses in the time it would typically take to finish one in the regular school program, thus allowing them to make up lost time. The students must maintain passing grades and not pose discipline problems in their regular courses to remain in the program. They may also lose the privilege of remaining in the program if they do not cooperate, by being "voted out" by fellow students. The majority of students who enter Project Stay on the verge of dropping out stay in school and graduate on time.

The instructional technology that enables classroom teachers to meet the needs of students of different skills levels is already available, but in many cases teachers do not have access to that technology. School psychologists can assist their school districts in learning about this technology and arranging for in-service programs to bring this information into the classroom. Instructional approaches such as mastery learning, adaptive education, team teaching, cooperative learning, peer tutoring, and curriculum-based assessment are all methods that have been shown to produce academic gains in students of all achievement levels (see Graden, Zins, & Curtis, 1988, for further discussion of these approaches).

Two examples of such approaches are one school district's decision to respond to high numbers of retentions in the early grades by implementing a curriculum-based assessment and remediation program to correct basic reading problems. The district, with state support, secured an outside consultant, conducted intensive in-services for teachers, and allowed a local school psychologist to develop expertise in the area and become an on-site leader. Enlisting community support to volunteer to review "sandwich word drills" with students garnered both help and excitement in the community. Children made substantial progress, teachers were excited by a new intervention method, and requests for retention dropped dramatically.

Similarly, another district has begun a systemwide program to provide in-service instruction to teachers in fostering metacognitive awareness and learning strategies in students, by helping teachers learn about metacognitive development and study skills training and learn how to embed instruction in these areas into their everyday teaching. Collaborative monthly meetings with a consultant and the training of Chapter I teachers to become on-site experts proved essential to this program's success. The program having been established at the primary level, the teachers in this district now speak less of retention and more of enabling strategies that can be carried over from grade to grade with at-risk students.

To be taught and implemented effectively, the program must gain from school districts a commitment to providing sufficient in-service training. School psychologists are often effective lobbyists for such continuing professional development. In making arguments for such training, school psychologists should help school administrators recognize the economic benefits of reducing retention rates. The National Education Association recently estimated that the average cost per pupil in this country is $4,509 per year (*NEA Today*, May 1989). If a school district, for instance, retains 30 students annually, adding 1 year to those students' school careers will cost districts or state educational agencies in excess of $135,000 each year. There is no doubt that quality training for teachers can be obtained at a far lesser cost.

Another district (Somersworth and Rollinsford School Districts, Administrative Unit 56) reduced retentions dramatically by putting in place a collaborative, problem-solving team to deal with problems prior to the necessity of referral. Retentions dropped from a peak of over 40 in the 1983–84 school year to just six in the 1990–91 school year in three elementary schools with an enrollment of 1,500. In addition, after the new model was put into place (through efforts of the local school psychologist), inappropriate referrals (those not leading to special education placements) and out-of-district placements also declined from 30 to 5, and from over 100 to less than 50, respectively, in a 5-year period.

State Education Agencies

As advocates for children, school psychologists can often be most effective when they move beyond the realm of their own schools and school districts to work at a state level to bring about change. The discrepancy between what is known about retention and what is practiced is great enough to warrant action at a higher level. While a school psychologist acting alone cannot influence state policies and practices, through the efforts of a state school psychology association, change can be effected.

School psychology associations are encouraged to share the research on retention with their state education agencies and with other professional education associations (such as state principals' and superintendents' groups). They are also encouraged to use the lobbying resources available to them to influence legislation, including funding for alternative services delivery and legislation that affects policy, such as decreasing the rigidity of minimal competency requirements. Associations are encouraged to make use of the NASP Position Statement of Student Retention and the Supporting Paper (Rafoth, Dawson, & Carey, 1988) in these efforts.

SUMMARY

While the research on retention is voluminous and much of it is flawed, most recent reviewers have concluded that there are no clear benefits to retaining students and that the practice can have deleterious effects on students' achievement, self-concept, and attitudes, and can increase the likelihood of dropping out of school. Research conducted since the release of the NASP Position Statement on Student Retention has continued to support these findings. Although it is possible that a small percentage of students retained may benefit, it is impossible to predict which students those will be. Use of transition rooms prior to first grade are no more effective than retention, and whatever initial benefits may be derived from retention after kindergarten or first grade appear to be washed out by the end of third or fourth grade. School psychologists should assist in making retention decisions about individual students and should promote effective alternatives to retention. Working to change school practices in the area of retention will require sharing the research on retention with educators, conducting evaluations on the outcomes of retention decisions at the local level, and lobbying at the state level to promote changes in policy and to advocate for alternative service delivery systems that more effectively meet the needs of students experiencing school failure.

ANNOTATED BIBLIOGRAPHY

Carstens, A. (1985). Retention and social promotion for the exceptional child. *School Psychology Review, 14*, 48–63.

This article reviews the theoretical and empirical support for retention, with particular focus on the exceptional learner. The assumptions and goals of retention are reviewed from several theoretical perspectives: Gesellian, behavior analysis, cognitive-developmental, and mastery learning. The author concludes there is a lack of empirical support for retention, nor is there basis for retention on theoretical grounds. Exceptional children, including slow learners, learning-disabled students, and students described as "immature" do not appear to benefit from retention, and the author urges schools to apply interventions that attempt to remediate specific skill deficits.

Gredler, G. (1992). *School readiness: Assessment and educational issues.* Brandon, VT: CPPC Publishing.

This book is divided into four sections which include (a) an introduction and review of the concept of school readiness; (b) an assessment of readiness through screening measures and their validity and usefulness; and the emotional and social adjustment of "young"-for-age children; (c) current practices in the schools such as variation in entry age and its effect on achievement; the use of transition rooms between kindergarten and first grade; retention, intervention/remediation programs for young children, and issues in early childhood education; and (d) related legal and ethical issues concerning readiness and early retention. It offers a comprehensive overview of all issues that touch on the practice of retention at the beginning of a child's education. He concludes that transition rooms and early retention are not effective and discusses alternatives.

Holmes, C. T., & Matthews, K. M. (1984). The effects of non-promotion on elementary and junior high school pupils: A meta-analysis. *Review of Educational Research, 45*, 225–236.

This study employed meta-analysis to integrate the findings of 44 studies investigating the effects of retention on elementary/junior high students. The results established consistently negative effects of retention on achievement, personal adjustment, and attitude toward school. The authors conclude, "Those who continue to retain pupils at grade level do so despite cumulative research evidence showing that the potential for negative effects consistently outweighs positive outcomes."

Medway, F. J., & Rose, J. S. (1986). Grade retention. In T. R. Kratochwill (Ed.), *Advances in school psychology* (Vol. 5). Hillsdale, NJ: Erlbaum.

This chapter on research considers the legal implications of retention and attempts to identify the best candidates for retention. It concludes with a discussion of the role of the school psychologist in making retention decisions.

Smith, M. L., & Shepard, L. A. (Eds.). (1989). *Flunking grades: Research and policies on retention.* New York: Falmer.

This volume provides a comprehensive review of the literature as well as a discussion of the editors' own research addressing policy and practice in student retention. Particularly noteworthy is their discussion of the relationship between retention and school dropout, in which they demonstrate that students of comparable achievement levels are more likely to drop out of school if they have been retained than if they have been promoted. The book concludes with recommendations for alternatives to retention.

Best Practices in Conducting Needs Assessments

Richard J. Nagle
University of South Carolina

OVERVIEW

School psychologists can play an active role in designing programs or services responsive to children's needs. Needs assessment is a systematic process of collecting and analyzing data in order to identify needs and problems to be addressed in program planning, development, and modification. School professionals must develop clear and comprehensive goals that are responsive to the realities of the school and community. Because services should be those that are required and desired, needs assessment serves as the foundation on which programs are formulated (Lewis & Lewis, 1983).

Definitional and Conceptual Issues in Needs Assessment

The most common model for identifying needs in the schools is the discrepancy between some current condition and some desired (or required) state (Kaufman & Zahn, 1993; McKillip, 1987). In comprehensive needs assessment, once these gaps or needs are identified, the evaluator must also identify and assess existing school and community services and other resources to meet these needs; develop priorities among identified needs; and determine which services should be maintained, altered, or newly developed.

A need also has been defined as a "value judgment that some group has a problem that can be solved" (p. 10, McKillip, 1987). In defining need in this manner, McKillip (1987) underscores several important considerations for those who conduct needs assessments. First, because needs involve values, different people may perceive different needs for the same situation. It is quite possible that those observing the needs may differ from the person experiencing them as to what the needs are. Nor is it uncommon for service providers to differ from service recipients in reported needs. Second, because needs may emerge for a particular "group," this implies there is an environmental context which will require careful description to facilitate needs analysis. This is particularly important in identifying groups which may be "at risk" for poor outcomes. Third, McKillip states that the definitional component of "problems" reflects an inadequate outcome that falls short of expectations. Lastly, McKillip suggests that recognition of a need implies a judgment that problems which are detected can be solved. Because problems may be created by multiple causes or factors, potential solutions must be judged by their probable efficacy in alleviating the problem, the general cost of the solution, and the feasibility and ease of implementation of the solution.

Bradshaw (1972) developed four distinct conceptual approaches in defining and measuring need. These categories are labeled normative need, relative need, perceived need, and expressed need. This categorization is useful in that it offers multiple perspectives of need as well as different but complementary approaches to comprehending need (Kettner, Moroney, & Martin, 1990).

A normative need implies the presence of some norm or standard, with need being evaluated against some standard. These standards are often set by experts, professional bodies, school boards, or governmental bureaus (Rothman & Gant, 1987). Normative expectations are particularly useful in program planning and in areas where there is a lack of prior experience (McKillip, 1987). Although normative information may be advantageous in providing program planners with objective targets, a potential shortcoming with this approach is that norms or standards may change.

Felt or perceived needs are what people think or perceive are their needs or expectations for services outcomes. Perceived needs are based on the presumption that individuals in the target population have insight into their own needs (McKillip, 1987). Whether that is the case or not, program planners may discover ways in which services can be designed to be responsive to client needs. Unlike normative need where a single standard exists, with perceived need the standard changes with each respondent (Kettner et al., 1990). Thus these data may be highly variable and individualistic. Also, once consumers are asked to report perceptions of their needs, expectations may be raised that program planners will implement programs that will meet their needs (Kettner et al., 1990).

An expressed need deals with the actual utilization of services. This approach provides an estimation of the percentage of people whose perception of need has been mobilized into action (Kettner et al., 1990); however not all those who need services seek them. Because the main focus of expressed need involves the utilization of current services or programs, they can result in solutions which maintain the status quo (McKillip, 1987). Waiting lists, requests for services that do not exist, and petitions are all indicators of expressed need.

Lastly, comparative or relative needs involve the comparison of one group with another. The disparity existing between the two groups is the criterion on which the existence and extent of need are established (Rothman & Gant, 1987). Unlike normative need, there is no standard comparison, but rather group comparisons. These could involve comparisons between elementary schools within the same school district or grade-level differences within the same school building, with the revealed gaps between levels of services in these groups indicating need. Program planners who make group comparisons should be vigilant to the unique sociocultural variables or environmental context among different groups to accurately explicate these differences.

As can be seen, all of these conceptualizations of need have distinct strengths and limitations. In the coming sections of this chapter, the reader will see that different methods of needs assessment emphasize certain conceptualizations of need. Given the limitations of each conceptual approach to need, multiple methods or techniques of needs assessment are often recommended to reduce bias in the identification of population needs.

Purposes of Needs Assessment for School Psychologists

The scope of a needs assessment can be very broad based such as at school district and/or community level, or much narrower in focus such as at the school, grade, or department level. Despite the possible breadth of scope of needs-assessment activities, there are several general purpose of needs assessment for school psychologists. As previously discussed, needs assessment can serve as the foundation for program planning, development, and modification. Needs assessment data may also provide information to decision-making bodies such as a school board to justify budgeting priorities. When a strong link between allocation of money and other resources and needed services is observed, decision makers demonstrate strong accountability for their actions. Additionally, identified needs among a target population in a school district may justify funding requests for internal funding or external sources of local, state, or federal grants.

Needs assessment may also be useful in promoting the professional development of school personnel. Training needs may be established and help design staff development activities (i.e., in-service training) which are both relevant and appropriate to improving job functioning among school personnel.

Lastly, dissemination of needs assessment data may serve an important informative function within the schools and/or community. This can serve as the basis for school and/or community awareness of what the needs are and which courses of action decision makers are considering in their problem solving.

BASIC CONSIDERATIONS

School psychologists may become aware of problems in service delivery in a variety of different ways. Because the role of a school psychologist will vary considerably from school district to school district, it also will differ relative to the psychologist's relationship with program planners.

Planning the Assessment Program

Establishing a need. One of the initial phases in conducting a needs assessment is to clarify the presenting problems or unsatisfactory state of affairs. According to Illback, Zins, Maher, and Greenberg (1990), these problem-clarification activities are aimed at providing "systematic information to place the problem(s) in context and to assure that appropriate planning occurs based on a clear understanding of service needs" (p. 807). This contextual analysis provides initial data regarding the nature and scope of these problem(s). Methods which have been suggested in the literature (Harrison, 1987; Illback et al., 1990) include review of school documents, reports, files, direct observations, and brief interviews with involved persons. These interviews should be conducted with program planners, as well as a diverse sample of school personnel in order to clarify the problem from different perspectives.

Another important dimension to the problem-clarification phase is that it allows the school psychologist to estimate how receptive the school and/or community will be to change. The opportunity and commitment for program planning by key persons must be present. The initiation of needs assessment without the prior commitment to use data for planning purposes is a waste of time and resources and will likely result in conflict within the school (Warheit, Bell, & Schwab, 1977).

Establishing a needs assessment team. A needs assessment team is a working group responsible for the planning, monitoring, and perhaps executing the needs assessment process (National Urban League, 1983). The size of the group is dependent upon the nature and scope of the needs assessment effort, but usually not more than 6 people is a manageable size, particularly if the project is at the school level. Furthermore, it has been suggested (National Urban League, 1983) that members of the needs assessment team be selected based on the criteria of familiarity and knowledge of the target population, community resources and institutions, and the organizational context in which the programs will operate.

The needs assessment team should appoint a director of the project. For purposes of this chapter, it is assumed that this role will be filled by a school psychologist. Because this person will be required to oversee the entire project, he or she should have sufficient technical expertise and leadership skills to fulfill this function. Other members should be individuals who work cooperatively in a group, are task oriented, are capable of making fair and objective decisions, and have a strong commitment for program planning in the area of demonstrated need (National Urban League, 1983).

In addition to personal characteristics, potential assessment team members should be considered from a variety of school and community institutions. This group may include teachers, parents, community leaders and decision makers, local university faculty, representatives from appropriate community agencies, school board members, school administrative personnel, or principals. If the needs assessment is being conducted at the school level, representatives from the Parent Teacher Organization or school advisory council should also be considered. The bottom line is that the assessment team should have sufficient breadth of viewpoint to comprehend the problem and be able to assess the feasibility of different assessment approaches. The inclusion of members who are decision makers, such as principals for school-level assessment or school administrators/board members for district-level assessments, is important to build in commitment and political influence for program development recommendations based on the final needs assessment report.

Once the needs assessment team has been established, the scope of the needs assessment must be determined. In addition to the scope of the project, the amount of resources available to conduct the project is an important consideration. Practical considerations of budget and personpower will influence the method and level of information which can be gathered during the assessment process. The team members also need to evaluate the degree of technical expertise necessary to carry out some of the tasks of the needs assessment. If none of the members has sufficient skills in research design and data collection and analysis, the hiring of a consultant with these skills should be considered. Alternatively, the assessment team may be able to recruit volunteers with these professional skills.

Frequently, the school psychologist may be the only person available to conduct the needs assessment. In the absence of an assessment team, the school psychologist may solicit input from individuals using the same selection criteria used to choose members of the assessment team.

Methodological Concerns

After the initial planning activities are completed, the assessment team must determine what information should be collected. Team members should specify critical issues to be studied and the information necessary to understand them. The information to be gathered should be both quantitative (e.g., percentage of target group children not receiving a particular service) and qualitative (e.g., possible barriers to receiving such services). It has been suggested (National Urban League, 1983) that this information should be sufficiently specific to indicate the extent of the problems, influences on the problems, community resources available to deal with the problems, and hypotheses about potential solutions. However, the gathered information should not be so overly complex that the assessment process becomes unmanageable, too time consuming, or beyond the resources or expertise available (National Urban League, 1983). If the assessment process becomes too burdensome in terms of time and energy, it may delay or detract from program development and implementation activities.

The next section of this chapter will describe methods of needs assessment with a discussion of strengths and limitations to each approach.

BEST PRACTICES

There are different methods of needs assessment. Each approach has its own set of advantages and disadvantages, which will be addressed, and each can be easily modified relative to the scope of the needs assessment (i.e., school level, school district level).

Resource (Program) Inventory

A resource inventory is a compilation of services available to the target group in a specific service area (McKillip, 1987). This information is typically gathered by surveying service providers in the local community and school district. The central aim of a resource inventory is to describe available services, with particular emphasis upon identifying who is providing services, what are the characteristics and eligibility criteria of clients receiving services, and what is the service capacity of the program. Programs are also characterized based on their geographical location and organizational setting.

Programs can also be described based on the utilization patterns of services offered by each program. The underlying assumption of this approach is that program participants are those in the population in need of services. Because utilization rates represent manifestations of problems that have already developed, they are not helpful in prevention planning (Rhodes & Jason, 1991). Likewise, resource inventories detail programs which have already been implemented; therefore, conclusions based on data drawn from this method may give a status quo, institutionalized orientation to program planning (McKillip, 1987).

An important outcome of a resource or program inventory is that it may reveal significant gaps in services as well as identify underutilized services. Furthermore, it may reveal that different agencies provide overlapping services. In times of limited resources and budgets within the schools, the reduction in the overlap of services will allow the allocation of resources into other areas of need.

Resource inventories are generally quick and inexpensive to conduct. Resource inventories are usually among the initial steps in a needs assessment. As already mentioned, the resource inventory can provide certain levels of information for program planning. When considered alone, a resource inventory does not indicate need. Gaps in programming may exist because such services are not needed. For this reason, resource inventories should be supplemented with measures of the extent of the problem and potential demand for services (McKillip, 1987).

Social Indicators

The social indicators approach to needs assessment presumes that need estimates can be inferred by considering selected social and demographic statistics that have been found to correlate highly with service utilization (Lewis & Lewis, 1983). These statistics are presumed to be "indicators" of need. Social indicators are particularly valuable in estimating "at-risk" populations.

Because many federal, state, and local agencies, including schools, are required to maintain statistical information (Illback et al., 1990), social indicator data tend to be readily available through government publications summarizing census and surveys. The *American Statistical Index* is a comprehensive guide to statistical publications of the U.S. Government (McKillip, 1987). Local governments, health organizations, schools, social services agencies, and law enforcement organizations may also be important sources of indicator information. Depending on the problem area being assessed, information from these sources may include socioeconomic status, racial composition, educational levels, health status, housing patterns, family integration, prevalence of delinquency, suicide rates, school dropouts, drug and alcohol abuse, special class placements, achievement test information, and the like.

A distinct advantage of the social indicator analysis is that information is readily accessible and generally can be gathered for low cost by persons with limited research expertise or technical skills (Warheit et al., 1977). Another advantage of the social indicator approach is that the local community or school district can be compared to other communities at the local, state, or national level. In large school districts or ones where individual schools serve diverse populations, it may be useful to compare schools on selected demographic, economic, educational, and social characteristics.

Despite the advantages of social indicator analyses, there are several limitations in this approach. Because this approach is inferential in nature, it assumes that certain social indicators are predictive of needs for services. To validate this assumption, substantial evidence based on the research literature and prior studies is essential. Data from large geographic areas may not pertain or generalize to smaller communities or rural areas of interest (Rhodes & Jason, 1991). Before rates can be compared, differences in population characteristics must be considered.

Although extensive indicator data are available, the form or extent of specific informational requirements may not be fully met. For example, the data you are interested in gathering about certain child characteristics is subdivided into age levels different than those you require. Can it be assumed that information for 6- to 16-year-olds is a valid comparison with the 6- to 12-year-olds in an elementary school?

School psychologists who use the social indicator approach to needs assessment must be vigilant to population shifts which may occur in the schools they serve. While social indicator information is reported over a long time interval, it is possible that some communities may undergo very rapid changes. For this reason, the initiation of indicator analysis can provide baseline data on school or school district demographic characteristics to monitor changes and help guide future needs assessment programs.

Surveys

Surveys are the most commonly used needs assessment methods. They are flexible in format and can be conducted as face-to-face interviews, phone interviews, or questionnaires with a wide range of respondents.

Methods. The school psychologist interested in using surveys to assess needs must determine which method is most appropriate for his or her purposes. The selection of which methodology to choose is generally based on the intended scope of the needs assessment, the technical expertise available to conduct the survey, and the time and resources needed to complete the project.

If the number of persons to be surveyed is relatively small, then interviews are probably the most efficient means of gathering information. Therefore, needs assessments conducted at the school level usually lend themselves to the interview format. The success of interviews is largely a function of the skillfulness of the interviewer. The interviewer must be able to establish trust and convey empathy in order for the respondent to answer questions without feeling self-conscious or suspicious. Additionally, the interviewer should be able to keep the respondent on subjects pertinent to the needs assessment. If skilled interviewers are not available, considerable time and expense can be incurred for training. A major advantage of interviews is that they can provide in-depth information (Kaman, 1986) about a broad range of topics, including demographic characteristics, needs, feelings, desires, and solutions to the problems the respondent is experiencing. The interview also allows the opportunity to explicate questions and to probe ambiguous answers given by the respondent. Interviews are particularly well-suited in surveying the needs of marginal individuals (McKillip, 1987).

There are several advantages and disadvantages in the use of interviews. They can be time consuming and expensive and do not lend themselves to sampling large numbers of respondents. Given the cost of face-to-face interviews, phone interviews may be a reasonable alternative. Conducting phone interviews tends to be faster, but generally speaking, establishing rapport tends to be more difficult. Research also indicates that the rate of refusal to participate is higher with phone interviews than personal interviews (Warheit et al., 1972). Phone interviews may be the method of choice when interviews need to be conducted over a geographically dispersed region. In this instance, traveling expenses may make face-to-face interviews prohibitive. All of these issues have different levels of importance depending on whether the school psychologist conducts interviews at the school, school district, or community level.

Questionnaires are generally the preferred survey method when large numbers of respondents are required. If the items are highly structured, the data are easily quantifiable. The development of an effective questionnaire requires a certain degree of technical expertise. There are a number of important considerations in writing questionnaire items. A basic assumption is that the questions will be understandable, elicit the desired information, and motivate respondents to participate. Several sources (Edwards & Thomas, 1993; Fowler, 1993; McKillip, 1987) provide excellent guidelines on writing and formatting questionnaire items. Because it is beyond the scope of the present chapter to provide an in-depth description of questionnaire construction, the reader is referred to these references. Some of the central concerns in questionnaire construction deal with ensuring an appropriate readability level of items for the respondents, controlling for social desirability of responding, selecting open- versus closed-ended questions, and the use of ranking versus rating questions (McKillip, 1987).

Once items have been written, the next step should be to pretest or pilot the items. This is usually accomplished by asking a small group of individuals from the proposed sample to complete the questionnaire. After this has been completed, respondents are asked to critique questions and wordings, to ascertain whether questions are providing the information for which they were intended. Failure to undertake item piloting may result in wasted time and resources. Poorly written and designed questions will also result in decreased response rates.

Questionnaires have a number of disadvantages. They can be quite costly when reproduction, transportation, telephone, and postage expenses are considered. Generally, respondent turnaround time is slow so that a significant amount of time may elapse before the completed survey is received. If the response rate is low, considerable time and effort will be spent in follow-up aimed at increasing questionnaire completion.

Whether interviews or questionnaires are selected as the survey method, an important methodological concern involves sampling. When the objective is to estimate the frequency of need in the general population, a representative sample of that population is required. In instances where information about a specific subgroup is required, purposive sampling is the methodology of choice (McKillip, 1987).

Key informants as respondents. Key informants are individuals presumed to be knowledgeable about the problem under consideration. It is assumed because of the nature of their work or position in the school or community they will have a good understanding of the needs of the target population. The selection of key informants is made by the assessment team. The scope of the needs assessment and the perceived problem area will determine who are the key informants. For community-based needs assessments, individuals may be selected from the areas of public office, welfare and social service, law enforcement, religion, health, mental health providers, and education. Needs assessments at the school and school district level may include school administrators, principals, department coordinators, guidance counselors, school psychologists, special education teachers, nurses, regular education teachers, and so forth.

In initiating the key informant approach, the assessment steering committee should construct an interview schedule or questionnaire which permits those conducting the survey to obtain comparable data from each of the informants (Warheit et al., 1977). The committee should also select a single method of data collection. The most frequently used technique is the personal interview because it permits face-to-face contact, an open exchange of ideas, and the best response rate (Warheit et al., 1977). Questionnaires and phone interviews, although they result in lower response rates, can also be used effectively.

If the key informant approach is well planned and a diverse sample of key informants is used, the needs assessor can receive a comprehensive impression of the needs of the school or community. Some of the advantages of this approach include:

- It is generally simple and inexpensive to conduct.
- Assessment is based on professional judgment and actual experience with the problem (National Urban League, 1983).
- Because many community agencies or, in the case of school-based needs assessment, an array of school personnel are involved, the groundwork for cooperation and the development of coalitions between agencies or groups can be laid.
- It can serve as the basis for effective program planning by creating organizational readiness for change and support initiatives in program development (Illback et al., 1990).

The key informant approach allows for the input of many people with different perceptions of the problem situation. However, because their individual views on needs are based on their own organizational perspective, they may be biased. Key informants may be unaware of some of the needs of those they serve or may not comprehend the needs of those who are unserved or underserved. It is for this reason that those using the key informant approach should evaluate the adequacy of the number and type of informants used.

While the key informant approach has some inherent problems, it can be a valuable first step in the needs assessment process. A careful synthesis of information gathered from key informants can help narrow the focus of the assessment by ensuring that only appropriate group meetings, questionnaires, and social indicator approaches are designed (Lewis & Lewis, 1983).

Client/community respondents. Survey methods can be conducted on a specified sample or the entire population. Information gathered in a school- or district-based survey can provide valuable information regarding the (a) frequency of the problem or need, (b) demand for available services in the system, (c) client viewpoints of the problem and needed services, and (d) acceptability of solutions to the problem. The most important advantage of this approach is that it *directly* assesses the problems and needs of the sample surveyed. Thus the client/community survey can locate specific individuals or groups in need and determine the type of services required and desired by the population (Balacki, 1988). Demographic and other characteristics of the population in need can also be determined.

When surveys are conducted at the client/community level, they can raise expectations that the problem area will be addressed by the schools. The survey process can be reactive in a positive way by marshalling support for program initiatives.

Surveys at the client/community level can be quite costly and are not cost effective to use when every new program or service is being considered (Lewis & Lewis, 1983). It is probably best justified for the purpose of cyclical reassessment of changing schools needs. Appropriate sampling techniques can reduce costs. The main limitation encountered with client/community surveys is that they may lack a broad-based perspective of a problem or need (National Urban League, 1983).

Structured Groups

Structured groups provide a supplement and alternative methodology to other needs assessment approaches already reviewed in this chapter. Structured groups can be the most "active and informative" approaches to needs assessment because they involve people in systematic problem analysis and discussion (Illback et al., 1990). Focus groups, nominal group techniques, Delphi technique, and community forums will be discussed.

Focus groups. Focus group methodology is a commonly used qualitative research approach used for exploratory or hypothesis generation and confirmation of results from other needs assessment approaches. Focus groups are guided discussions intended to yield information on specific topics relating to feelings and beliefs about needs from a selected population (Sussman, Barton, Dent, Stacy, & Stag, 1991).

Focus groups are lead by a well-trianed facilitator knowledgeable about the problem under study. The discussion is typically begun by asking broad, open-ended questions about the problem with questions becoming increasingly more specific. The size of focus groups is usually 6 to 10 people. Homogeneous grouping is essential to allow free interaction among group members (McKillip, 1987). The criteria for selecting members (i.e., age, ethnicity, etc.) are determined by the objectives of the study; however, several groups with varied characteristics may be involved to learn more about subgroups in the population (Ward, Bertrand, & Brown, 1991).

Focus groups may be viewed as being quite similar to open-ended interviews. Research, however, indicates that focus groups are frequently superior to individual interviews because of the "synergistic group effect" which results in more identified needs and solutions (Sussman et al., 1991).

Focus groups are frequently used in conjunction with other needs assessment methods. They are useful in helping explicate differences between professional (key informant) and target (clients/community members) audiences. Many needs assessors use focus groups to aid in the construction of questionnaires by identifying issues to be addressed in the survey and to determine terminology and phrases used by the target population to describe their needs and solutions to those needs. Focus groups can also be used to gather responses to conclusions generated from other needs assessment methodologies.

Nominal group technique. The nominal group technique (NGT) was developed by Delbecq and Van deVen (1971) to overcome the common problems of group dynamics including domination of talking by high status group members, non-involvement of reticent members, evaluation of ideas impeding idea generation, and group tendencies to get off-task from the agenda (McKillip, 1987). The NGT was designed to give individuals with disparate interests, capabilities, information, or influence more equity in the decision-making and priority-setting process (Lauffer, 1982). The term *nominal* describes the process of bringing groups together but minimizing verbal communication (Miller & Hustedde, 1987).

The NGT requires a well-trained group leader or facilitator. The group can be comprised of key informants, clients, teachers, students, or service providers (McKillip, 1987). Although there are a number of variants in the NGT, most involve the following steps (Frankel, 1987; Miller & Hustedde, 1987).

1. Facilitator of group presents a problem or question that is clearly defined (e.g., How can we prevent school violence?).

2. Each group member is asked to write down independently and silently as many solutions on a piece of paper or index cards as they can think of. At this point, no discussion is permitted.

3. Each group member presents one solution or idea, one at a time in a round robin fashion. The facilitator records each idea on a flip chart until all are recorded.

4. After all solutions are recorded, they are clarified and evaluated through discussion.

5. Group members are asked to either secretly rate each proposed solution or to rank order their top five choices.

6. Ratings are tabulated and a summary of the results is presented.

7. If clear choices and/or priorities result from the vote, the NGT is complete. In the event of no choices, additional clarification, discussion, and voting are undertaken until a clear choice is obtained.

8. The cycle is repeated for each problem or solution area.

The priorities established by the group may not be accepted by others in the school or community. To minimize this possibility, the needs assessor should develop a plan that has adequate representation among subgroups in the school or community.

Delphi technique. The Delphi technique was developed to get group opinion among experts or individuals with exceptional knowledge about a particular subject area. This technique was developed at the Rand Corporation in the early 1950s to solicit opinion from military officials regarding the number of bombs needed in the event of war (Miller & Hustedde, 1987). Although educational decision making does not deal with such dire issues, the Delphi technique has been used successfully in school program-planning activities.

The Delphi technique typically starts with the assessment team determining which needs will be assessed, who will participate in the process, and how the information will be used. Based on what will be assessed, a questionnaire is developed.

The Delphi technique elicits expert opinion through the use of successive questionnaires administered to individual "panelists," selected on the basis of their expert knowledge or opinion (Lauffer, 1982). The process is designed to forecast or predict events when inadequate information exists. The format of the Delphi method is quite variable relative to the number of questionnaires sent to the panel. For most school applications, three questionnaires are probably adequate if using a panel of 8 to 12 experts.

Miller and Hustedde (1987) have outlined the basic steps in having panelists complete the series of questionnaires. In the first questionnaire, respondents are asked to answer questions regarding a problem situation. The questionnaire is returned and summarized and serves as the basis of the second questionnaire. Panelists are requested to rank their concerns, agree or disagree with the central tendencies of the group, and clarify their judgments. The purpose of this second questionnaire is to portray agreements and disagreements in priorities. A third questionnaire is then mailed asking respondents to reassess prior answers and to clarify their ratings relative to the group. They are again asked to vote by ranking the items listed on the questionnaire. This process is complete when there is general agreement among panelists. In the event of substantial differences among panelists, the questionnaire refinement-feedback cycle is continued. The central aim of the Delphi technique is to clarify problems and needs, not reach group consensus. Once the process is complete, respondents should be provided with a final report.

The Delphi technique is usually blended with other need assessment techniques. It can be effectively used to avoid confrontation when severe disagreement is likely to emerge among experts (Lauffer, 1982). This technique may also be a cost-effective way of gathering expert information by avoiding the high cost of travel.

The Delphi technique requires that respondents have well-developed writing skills as well as a high level of motivation because no facilitator is present to help stimulate responses (Miller & Hustedde, 1987). Although the length of time to conduct a Delphi panel will vary as a function of the number of questionnaire mailings, it typically takes about two months to complete the process.

Community forum. The community forum is similar to a town meeting in which the views and opinions of community members about their needs and problems are gathered. The community forum is appealing because it is generally easy to arrange and can be conducted inexpensively. The community forum can be easily adapted to the scope of the needs assessment in the schools. If the scope of the assessment is at the school level, the forum can be held at an individual school, while a district-wide needs assessment may involve a sample of schools or all schools within a given district.

To enhance the effectiveness of a community forum, a certain degree of planning is required. First, the needs assessment planning team should prepare questions designed to structure the meeting around the issues and, at the same time, provide sufficient flexibility to allow for spontaneous comments and candor among the participants (Warheit et al., 1977). The meeting should be highly publicized through advertising and the media and held at a convenient time and accessible location, because it is essential that a representative sample of the community attend. Early evening meetings at the local school in the community member's attendance area fit these criteria.

A leader for the forum should be appointed by the needs assessment team. This individual should have sufficient skills to keep the audience discussion on track. The leader must clearly state the purpose of the forum and explain any ground rules which will be used, such as time limits on talking by participants. In the event of very large turnouts for the forum, it may be necessary to divide the groups into smaller sections to facilitate discussion. Obviously, in these instances, several group leaders will be necessary. A person from the needs assessment team should also be present to record the proceedings of the meeting. The group leader may also wish to take a vote on priorities and concerns. A sign-up sheet for all participants should be used, so that follow-up mailings can be sent to those attending the meeting.

The advantages and disadvantages of the community forum approach have been discussed extensively by several authors (Lewis & Lewis, 1983; McKillip, 1987; Warheit et al., 1977). The community forum is easy to conduct, quick, and cost effective. The community forum allows for input from many segments of the community. The needs assessor may, in fact, become aware of some highly unique or unanticipated needs when the source of information is directly from potential service recipients. The community forum builds rapport and trust with the community and can enhance community members' commitment to program planning. It also identifies citizens who may be valuable resources for the later implementation of programs.

The validity of data gathered from a community forum will largely be a function of the representativeness of the group. Only a partial view of the community's needs or problems will be portrayed if the group is not representative of the general community. It is quite common for community members with severe problems or impairment not to attend a community forum. The forum leader must keep participants focused on the agenda, or else the meeting will degenerate into a gripe and grievance session. The forum leader must also avoid the meeting becoming controlled by special interest groups who wish to espouse their viewpoints, at the expense of not allowing others to offer opposing or different viewpoints. Similar to other needs assessment methods, the community forum raises expectations that something will be done to solve problems or to satisfy unmet needs.

The community forum is frequently used in needs assessment activities in the schools and is commonly used in conjunction with questionnaires to assess the "felt" needs of the community. The community forum approach is impressionistic and assumes that citizens are aware of and knowledgeable about their own problems and needs.

Selection of Needs Assessment Methods

As this chapter illustrates, needs assessment methods vary considerably in terms of their comprehensiveness, cost, and time necessary to complete the project. Many believe that cost and time should be held to a minimum so as not to interfere with other goals in the program planning process (Hobbs, 1987; Steadham, 1989). In performing needs assessments, no component is more important than the clear specification of the purpose and what you wish to accomplish in the needs assessment. The purpose and who you wish to influence are the most central criteria in choosing methods (Hobbs, 1987).

There are a number of additional criteria to consider when choosing a needs assessment method. These include the resources required and available for needs assessment activities, the skills of the needs assessment team, characteristics of the client system, preferred methods of the decision makers, and the allowable time frame for the needs assessment project (Steadham, 1989).

Because all needs assessment methods have inherent strengths and limitations, many needs assessors have advocated the use of multiple methods. By adopting this strategy, the potential limitations of one approach can be minimized by the use of an additional, complementary method. Multiple activities will also help estimate the reliability and validity of the results of the needs assessment.

Communication of Needs Assessment Findings

A successful needs assessment provides information, via reliable and valid methods, that will be used for program planning, development, and modification (Aponte, 1983). The effective communication of the results of the needs assessment to decision-makers is important because it will determine if the findings are used for program planning (McKillip, 1987). Decision makers will not act upon needs assessment information that they do not understand.

The scope and framework of the final report of the needs assessment depends on the audience to be addressed. The communication must fit audience interests, keeping in mind that they are busy and often unsophisticated about research methodology (McKillip, 1987). In instances where the needs assessor will report the findings to several audiences with divergent interests, modifications in the report may be necessary. While needs assessors focus on the results of the project, program planners are concerned with the organizational consequences of their decisions (Aponte, 1983). The findings should be reported to correspond to the questions raised by the decision makers.

The findings of the needs assessment can be presented in written and/or oral form. Warheit et al. (1977) has suggested the following outline for the needs assessment report:

1. Statement of purpose.
2. Historical background.
3. Design and methods.
4. Presentation of findings.
5. Listing of priorities and recommendations.

Written reports should be free of jargon or technical terms and provide only necessary information which will facilitate decision making. Poor grammar, typographical errors, and the like should be avoided because they will detract from the credibility of the report. The visual display of the findings also tends to facilitate clarity and understanding.

If an oral presentation is used, the needs assessment team must be sure that the presenter will be articulate, knowledgeable, and enthusiastic about the findings. Oral presentations can be greatly enhanced by handouts of the major findings of the needs assessment. Overheads or slides are also a useful means of avoiding "information overload" by audience members. A distinct advantage of the oral presentation is that it allows for personal contact with the exchange of information and occurs at a specified time (McKillip, 1987). Written and oral briefings are typically combined in needs assessment activities.

Whether or not the school or organization accepts the recommendations generated by the needs assessment report will be determined if the proposed changes (a) are based on factual data from the needs assessment, (b) are rank ordered by time-cost benefits, (c) are achievable, and (d) reflect the best interests of the school (Warheit et al., 1977). The problems associated with resistance to change will need to be considered at this juncture. Excellent discussions of these issues can be found in Harvey (1990), Kaufman and Zahn (1993), and Warheit et al. (1977).

SUMMARY

This chapter sought to introduce the reader to the use of needs assessment in the schools. A number of different needs assessment methodologies were explored, with the strengths and limitations for each approach discussed.

Needs assessment serves as the foundation on which programs in the schools are designed. Depending on the resources available in the school districts in which they work, school psychologists can play an active role in needs assessment activities. The unique training of school psychologists makes them viable members of needs assessment teams in the schools.

ANNOTATED BIBLIOGRAPHY

National Urban League. (1983). *A guide for developing non-instructional programs.* New York: Author. (ERIC Document Reproduction Service No. ED 272 597)
This reference provides an excellent step-by-step guide in designing school programs. It includes major sections on needs assessment, program planning, program implementation, and program evaluation. Using their experiences with Follow Through programs, the authors provide an actual case study on program planning.

Fowler, F. J. (1993). *Survey research methods* (2nd ed.). Newbury Park, CA: Sage Publications.
This book is among the best sources available on how-to-do surveys. There are particularly helpful chapters on sampling, item writing, interview methods, data analysis, and the ethical issues involved in survey research. This is an indispensable source for school psychologists interested in using surveys for research or program development.

Lauffer, A. (1982). *Assessment tools for practitioners, managers, and trainers.* Beverly Hills, CA: Sage.
This book was designed to acquaint professionals with the use of various structured group methods in needs assessment activities. Chapter 4 provides an excellent overview and case study of the nominal group method. Chapter 5 discusses the Delphi method as well as presenting several actual applications of this method.

Harvey, T. R. (1990). *Checklist for change: A pragmatic approach to creating and controlling change.* Boston: Allyn & Bacon.
This is an easy-to-read book dealing with the problems associated with organizational change. The author provides a step-by-step analysis of facilitating change with particular emphasis on how to overcome resistance to change and how to institutionalize change. The book contains many useful forms to evaluate the various steps in the change process.

Warheit, G. J., Bell, R. A., & Schwab, J. J. (1977). *Needs assessment approaches: Concepts and methods* (Publication No. ADM-77-472). Washington, DC: Department of Health, Education, and Welfare.
This U.S. Department of Health, Education, and Welfare publication continues to be one of the key sources on how to conduct needs assessments. Using a community emphasis, this publication provides many practical suggestions including how to form a team, select methods, construct questionnaires, do sampling, and supervise a needs assessment team. This book has stood the test of time and serves as an excellent introduction to needs assessment.

Best Practices in School Discipline

George G. Bear
University of Delaware

OVERVIEW

Since the onset of public schooling, school discipline has been a foremost concern among both educators and parents. The public has always demanded that schools *teach self-discipline*, the self-regulation of behavior, for the good of society. Upon reaching adulthood, individuals are expected to function autonomously — to assume responsibilities associated with citizenship in a democratic society. The public also has demanded that schools *use discipline*, not only to teach habits reflecting self-discipline, but also for the purposes of maintaining an orderly environment conducive to academic achievement and developing socially and morally responsible individuals.

Whereas these two societal expectations have changed little over the years, the nature of the socialization task has changed markedly. Teachers must still contend with children talking in class, getting out of their seats, not completing their work, and exhibiting many other violations of social conventions. But added to this list in recent years have been a growing number of much more serious problems: verbal and physical aggression against teachers, use of guns and knives, drug use, vandalism, gang violence, and the like. Teachers are now expected to teach self-discipline and to use discipline in dealing with these moral transgressions, and often to do so with little help from the traditional sources of social support outside of the school — the home, the church, and the community.

In this chapter, *discipline* refers to (a) instruction designed to teach *self-discipline* and (b) *disciplinary actions* used to deal with behavior problems when they occur. Self-discipline reflects internal motivation for one's behavior. It entails self-directed inhibition of antisocial behaviors, moral and social responsibility for one's actions, understanding of right from wrong, and appreciation of the importance of cooperative relationships in the classroom and society. Self-discipline is most evident when external regulators of behavior (e.g., presence of adults, clear rules) are absent.

Because children rarely demonstrate self-discipline across all behaviors and settings, it is well recognized that externally based disciplinary actions also must play a necessary and crucial role in the educational process. Too often, however, educators have failed to recognize that the teaching of self-discipline, not the external control of behavior, is the ultimate goal of social education. Externally based disciplinary actions, although necessary for achieving immediate objectives in the classroom, are not sufficient for achieving the more long-term goals of self-discipline.

In light of the wide range and complexity of behavior problems, it is clear that educators must adopt comprehensive and broad-based models of discipline if they hope to achieve the dual goals of teaching self-discipline and managing misbehavior. Included in a broad-based school-wide model of discipline should be a prevention-oriented component focusing on the teaching of self-discipline, an intervention component designed to deal with common disciplinary problems, and a treatment-oriented component. Whereas the first two components would be for all children, the treatment-oriented component would be for students experiencing serious behavioral/emotional problems and those at risk for such problems.

BASIC CONSIDERATIONS

The topic of discipline cuts across multiple literatures, including child development (primarily under the rubrics of socialization, child-rearing, aggression, juvenile delinquency, self-regulation, moral development, and prosocial behavior), education (under classroom management, school climate, and character education), guidance and counseling (counseling techniques, affective education, crisis intervention), and school psychology (personality assessment, consultation, intervention techniques, intervention acceptability). In addition to keeping abreast of recent developments in theory, research, and practice in these areas, school psychologists need to remain aware of current legal, ethical, and political issues

407

pertaining to discipline. For example, school psychologists should recognize that participation in "psychological" or "affective" programs and activities has been challenged successfully by parents who argue that federal law (i.e., the Hatch Amendment) guarantees them the right to exclude their children from participating. Thus, parental permission may be necessary for students to participate in those preventive activities (e.g., values clarification and moral discussion activities) which have commonly been viewed by educators as being harmless.

Corporal punishment defined as the "intentional infliction of physical pain, physical restraint, and/or discomfort upon a student as a disciplinary technique" (National Association of School Psychologists [NASP], 1988) and, to a lesser degree school expulsion, also have generated increased controversy in recent years. Despite greater public recognition of its many limitations and the passage of state laws restricting its use, corporal punishment continues to be used in America. Indeed, half of the American public view corporal punishment favorably (Gallup & Elam, 1988). Clearly, a best practice in dealing with discipline problems is to first become familiar with the disadvantages of punitive approaches (see Hyman, 1990); NASP's (1986) position on the use of corporal punishment; and local school policies related to the use of suspension, expulsion, and other disciplinary procedures.

BEST PRACTICES

Models of discipline most commonly have been organized according to their underlying theoretical perspective. Hyman, Flanagan, and Smith (1982) grouped discipline models into five basic categories: psychodynamic-interpersonal, behavioral, sociological, eclectic-ecological, and human-potential. Others have organized models of discipline according to the processes, strategies, and techniques emphasized. For example, Wolfgang and Glickman (1986) provided a useful process-oriented framework in dividing popular models of discipline into three major categories.

Relationship-Listening models, such as Teacher Effectiveness Training (Gordon, 1974), Transactional Analysis (e.g., Harris, 1969), and Values Clarification (Raths, Harmin, & Simon, 1966) emphasize effective communications, interpersonal relations, and the importance of a classroom environment that fosters free expression of feelings, self-esteem, and self-directed problem solving. Active listening, nondirective statements, and questioning are the strategies of choice.

Confronting-Contracting models, such as Glasser's Reality Therapy (Glasser, 1969, 1975) and Dreikurs' model of discipline (Dreikurs, Grunwald, & Pepper, 1982) emphasize the reciprocal interaction of cognitions, feelings, environmental factors, and overt behavior. Strategies commonly used are questioning, directive and nondirective statements, modeling, reinforcement, and physical intervention or isolation.

Rules/Rewards-Punishment models, such as Assertive Discipline (Canter & Canter, 1976), emphasize environmental control of behavior. Behavior modification techniques are employed, including directive statements, modeling, reinforcement, punishment, physical intervention, and isolation.

Perhaps a more functional way to conceptualize the multiple models of discipline is to focus primarily on the goal(s) of each model and secondarily on the processes, strategies, and techniques used to achieve the goal(s). Three main categories of discipline models thus could be identified:

1. Preventive Discipline (models primarily intended to prevent misbehavior and develop self-discipline).

2. Corrective Discipline (models that primarily address ways to deal with acts of misbehavior).

3. Treatment Discipline (those models designed primarily to treat students with chronic behavior problems or to provide extensive services to those children who are "at-risk" for developing serious conduct problems). (Bear, 1990)

Preventive Models

If one's primary concern is the development of self-discipline and the prevention of misbehavior, then strategies and techniques associated with preventive models should be of primary focus. These models share a common purpose: To teach children behaviors, cognitions, and emotions which characterize democratic ideals, especially self-discipline, respect of self and others, social and moral responsibility, empathy, and caring. They differ, however, in goals, strategies, and techniques emphasized.

Preventive classroom management model. Advocates of this model (e.g., Bauer & Sapona, 1991; Emmer, Evertson, Sanford, Clements, & Worsham, 1989; Evertson, Emmer, Clements, Sanford, & Worsham, 1989) recognize that effective teachers curtail misbehavior and foster academic achievement by keeping students actively involved in appropriate academic activities. Activities are presented at the correct pace and instructional level, are motivating, and help promote norms for behavior and work.

Effective teachers manage the classroom successfully by creating and maintaining orderly learning environments (Doyle, 1986). Beginning with the first week of school they present clear rules and procedures and follow predictable routines. Throughout the year they frequently monitor classroom behavior and consistently enforce classroom rules. Many behavior problems are anticipated and thus avoided. When behavior problems do occur they are re-

TABLE 1
Popular Models and Techniques for Dealing with Discipline Referrals

Model	Techniques Emphasized
	Models and Techniques That Focus on Prevention
Classroom Management Model	Effective teaching practices, including frequent monitoring, clear rules and procedures, and social praise.
Prosocial Behavior Model	Systematic reinforcement, modeling of prosocial behaviors, verbal instruction, role-playing.
Moral Education Models	
Cognitive developmental	Classroom moral discussions, role playing, student participation in school government.
Character education	Reading of moral literature, direct teaching of values, practice of prosocial habits.
Social Problem-Solivng Model	Direct teaching of SPS skills such as Model alternative thinking, means-end thinking, and the like; self-instruction training, dialoguing.
Peer Mediation Model	Teching of conflict resolution skills, cooperative learning.
Affective and Communication Models	Values clarification activities, active listening, communication and interpersonal skills training for students and teachers.
	Models and Techniques That Focus on Correction and Control of Misbehavior
Behavior Management Model	Direct instruction; reinforcement techniques including social praise, material reinforcers, tokens; punishment-oriented techniques, including verbal reprimand, response cost, time-out; group contingency techniques; behavioral contracting; self-management.
Reality Therapy Model	Confrontational questioning; classroom meetings, classroom moral discussions, social problem-solving, behavioral contracting, logical consequences, time-out, preventive techniques such as democratic governance.
	Models and Techniques That Focus on Treatment
Social Skill Training Model	Direct instruction, modeling and rehearsal, coaching, self-instruction, manipulation of antecedents and consequences.
Aggression Replacement Training Model	Social skills training techniques, self-instruction (Anger Control Training), moral discussions.
Parent Management Training Model	Parent training in application of behavioral techniques.
Family Therapy Model	Variety of therapeutic and educational techniques, depending on particular model.
Behavior Therapy	Variety of cognitive-behavioral and operant techniques.

sponded to immediately and in a manner that causes the least amount of classroom disruption.

Effective classroom managers ensure that more public attention is paid to academic work than to misbehavior. As such, they praise children often and strategically, being sincere and not overly effusive (see Brophy, 1981). They also recognize that certain physical arrangements and activities tend to invite misbehavior, such as transitional periods, recess, lunch, long student presentations, and other activities in which students move about frequently. Monitoring of behavior is increased during these times.

It is clear that teachers can prevent frequent misbehavior by establishing and maintaining an orderly climate in which students are sustained in work-related behavior. However, it also is clear that teachers should not equate preventive classroom managemnet with authoritarianism. Goldstein and Weber (1981) found that whereas group process and socioemotional climate approaches to discipline (similar to the

BEST COPY AVAILABLE

confronting/contracting models) were associated with appropriate classroom behavior, the authoritarian approach was not.

Prosocial behavior model. Preventive classroom management and prosocial behavior models share many strategies. However, rather than focusing on the ecology of the classroom and managerial procedures, the prosocial model emphasizes the use of specific behavioral techniques to teach and reinforce appropriate social behaviors. According to this model, which is largely derived from social learning theory, behavior problems are prevented by teaching and maintaining such prosocial behaviors as sharing, helping, caring, and cooperating. The ultimate goal is to teach students to behave prosocially in the absence of external rewards (i.e., for children to become self-disciplined). Three types of behavioral techniques most commonly are employed, typically in combination with one another:

- Systematic reinforcement of desirable behaviors (using either social-, material-, or self-reinforcement).
- Exposure to prosocial models.
- Strategic use of verbal instruction.

Although the prosocial model clearly provides effective classroom techniques for preventing and correcting discipline problems, its reliance on external monitors of behavior has caused many educators to question its value in the teaching of self-discipline (see Doyle, 1986).

Moral education models. Moral education is "whatever schools do to influence how students think, feel, and act regarding issues of right and wrong" (Association for Supervision and Curriculum Development, 1988). It includes nearly all aspects of discipline: The moral and social climate of the classroom, self-control, values and goals, moral reasoning and social decision making, and prosocial behavior. Most preventive models of discipline also can be considered moral education models, and vice versa.

Derived largely from the works of Dewey, Piaget, and Kohlberg, the *cognitive-developmental model* of moral education posits that children simply do not acquire normative behavior via reinforcement, punishment, and modeling, but do so by acting on their environments. That is, self-discipline evolves from within the individual — it is not only a consequence of external control: Although clearly influenced by one's environment, children think and reason for themselves. A major aim of the cognitive-developmental model of moral education is to facilitate children's development of mature moral reasoning. Immature moral reasoning, especially that reflecting an egocentric and hedonistic perspective, has been associated with juvenile delinquency (Blasi, 1980) and a variety of classroom behavior problems (Richards, Bear, Stewart & Norman, 1992), and peer rejection (Bear & Rys, in press).

Moral discussion, role playing, and active participation in school decision making are the major educational strategies used to promote mature moral reasoning. Programs based on the cognitive-developmental model have been effective not only in fostering the growth of moral reasoning (see Bear, 1987) but also in improving the moral climate of the school (Power, Higgins, & Kohlberg, 1989). The moral discussion approach also has been a component of successful programs designed for the treatment of serious behavior problems (Arbuthnot & Gordon, 1986; Gibbs, Arnold, Cheesman, & Ahlborn, 1984; Goldstein & Glick, 1987).

The cognitive-developmental model of moral education recently has been challenged by a new model — the *character education* model of moral education. Critical of the cognitive-developmental model's focus on reasoning and its lack of emphasis on actual behavior, proponents of this model (e.g., Kilpatrick, 1992; Wynne & Ryan, 1993) argue for an old-fashioned emphasis on developing virtues or character traits (e.g., honesty, truthfulness, industry). This is achieved by means of literature that highlights such traits (i.e., modern-day versions of the *McGuffey Reader*), the practice of good habits (e.g., community and school service), ceremonies and assemblies that recognize values, and strict codes of discipline. Whereas the recent character-education model appears promising, it has yet to develop a research or theoretical base.

Perhaps the most exemplary model education project, one that incorporates major elements of the cognitive-developmental model and the character-education model, is the Child Development Project (Battistich, Watson, Solomon, Schaps, & Solomon, 1991), a program being implemented in several school districts across the country. This comprehensive program uses a combination of strategies, including moral discussion, moral literature, highlighting of prosocial values, and cooperative learning, to develop children's prosocial reasoning, interpersonal understanding, values, and prosocial behaviors.

"Developmental discipline," an important component of the Child Development Project, focuses on developing self-control and internalization of prosocial values. It balances the developmental needs of the students with the classroom management needs of the teacher. Whereas teachers use a wide variety of developmentally appropriate strategies to promote self-discipline and intrinsic motives for prosocial behavior, they also set clear standards for appropriate behavior and enforce these standards. Teachers strive to develop moral and social reasoning and to build a sense of school community which is characterized by warmth, sensitivity, and open communication. Research has shown that compared to students in non-program schools, children in the Child Development

Project exhibit more prosocial behavior, have better-developed conflict resolution skills, and hold more democratic views (Battistich, Watson, Solomon, Schaps, & Solomon, 1991).

Social problem-solving model. Targets for instruction in the social problem-solving model are specific thinking skills lacking in aggressive children (Asarnow & Callan, 1985). The skills most commonly taught are alternative thinking, consequential thinking, social-causal thinking, means-ends thinking, and sensitivity to problems (Spivack & Shure, 1982). Advocates of this model claim that social problem-solving skills mediate interpersonal behavior and that the teaching of these skills generalizes to multiple settings and behaviors.

Behavior modification and cognitive modeling techniques are used to teach students sequential problem-solving steps directly. For example, in Gesten and Weissberg's curriculum, students learn to apply the following eight steps when faced with interpersonal problems:

1. Look for signs of upset feelings.
2. Know exactly what the problem is.
3. Decide on your goal.
4. Stop and think before you act.
5. Think of as many solutions as you can.
6. Think ahead to what will probably happen next after each solution.
7. When you think you have a really good solution, try it.
8. If your first solution doesn't work, try again! (Gesten, Weissberg, Amish, & Smith, 1987)

An attractive feature of this process, and others like it, is that it integrates affective, cognitive, and behavioral dimensions of social problem solving.

An additional technique used in social problem-solving programs is *dialoguing*, an intervention process in which the instructor guides students through the social problem-solving steps via questioning and cognitive modeling during actual situations of interpersonal conflict. In Shure's (1992) *I Can Probelm Solve* program, which combines dialoguing with the direct teaching of thinking skills, the following steps are recommended during dialoguing: (a) Ask the child to define the problem; (b) elicit feelings; (c) elicit consequences; (d) elicit feelings about consequences; (e) encourage the child to think of alternative solutions; (f) encourage evaluation of the solution; and (g) praise the child's act of thinking.

Although several studies have indicated that social problem-solving training is effective, others have not (see Coleman, Wheeler, & Webber, 1993; Denham & Almeida, 1987). Not all social problem-solving skills have been shown to mediate social behaviors, nor have many programs been successful in producing improvements in behavior that generalize across settings. Nevertheless, in a comprehensive literature review Kazdin (1987) concluded that social problem-solving training is one of the most promising programs for treating antisocial children.

Peer mediation. Programs designed to teach students to play an active role in settling disputes and handling classroom disciplinary problems have increased in popularity over the past few years. These programs are grounded in the philosophy that self-regulation is more important than external control of behavior and that students can be trained and empowered to resolve conflicts on their own. Perhaps the most developed peer mediation program is the Peacemaker Program (Johnson & Johnson, 1991; Johnson, Johnson, Dudley, & Burnett, 1992) in which students are taught the conflict resolution skills of negotiation and mediation. In negotiating and mediating classroom conflicts a variation of the social problem-solving model is followed by teacher-appointed peer mediators who wear official T-shirts while assuming "peacemaker" duties. Their goal is to facilitate a joint decision-making process that will result in solutions that are acceptable and fair to all parties involved.

Although much research remains to be conducted on the Peacemaker program, the program appears promising. Johnson et al. (1992) report that it was effective in reducing both the incidence of a variety of behavior problems and the need for teacher-imposed interventions.

Affective and communication models. Affective and communication models are typically atheoretical or humanistic in orientation. These models focus on feelings, self-concept, interpersonal communication, and values. In addition, they emphasize the importance of a classroom climate in which teachers effectively communicate with students by demonstrating empathetic understanding, warmth, and acceptance. Values are addressed in a non-indoctrinative and non-judgmental fashion. The teacher functions as a therapist-like facilitator who wisely uses active listening skills that promote communication, expression of feelings, and clarification of values.

Affective and communication models have generated a wealth of popular curriculum materials and programs. Examples include *Developing Understanding of Self and Others* (Dinkmeyer & Dinkmeyer, 1982), *Teacher Effectiveness Training* (Gordon, 1974), and *Values Clarification: A Handbook of Practical Strategies for Teachers and Students* (Simon, Howe, & Kirschenbaum, 1972). These programs generally rely on the use of role-playing, classroom discussions, games, and activity worksheets. They vary greatly in terms of scope, comprehensiveness, and primary focus. Given their comprehensiveness and the methodological difficulties in measuring affective goals, it is not too surprising that only a few studies have demonstrated the effectiveness of these models (see Leming, 1981; Strein, 1988, for reviews).

Models for Dealing with Discipline Encounters

Disciplinary encounters are likely to occur whenever a teacher perceives misbehavior as disrupting or threatening the order of a classroom activity, especially if the behavior is highly visible and contagious (Doyle, 1986). What follows is an overview of three popular models that use a variety of practical techniques and strategies to deal with disciplinary encounters. Many of the preventive strategies and techniques cited previously can, and *should*, be used when dealing directly with discipline-related problems. This would include social problem solving (including dialoguing), active listening, modeling, role-playing, and moral discussion. Depending on the behavior problem, use of these techniques communicates to students that misbehavior is inappropriate and must be corrected. However, many disciplinary encounters call for additional measures, used alone or preferably in combination with preventive-oriented techniques. Thus, added here are those techniques that focus more on the correction and control of misbehavior, rather than its prevention. Because of limited space, only three models representing best practices in dealing with intervention during disciplinary encounters are highlighted.

Behavior management model. For years teachers have responded to classroom misbehavior with punishment-oriented behavioral techniques. The most popular among these techniques have been verbal reprimands, response cost (e.g., loss of earned recess time or privileges), and time-out (e.g., making the student sit alone or sending the student to the principal). To a lesser extent teachers also have used positive reinforcement techniques such as privileges, material reinforcers, and tokens to bring about behavioral change (Kazdin, 1982). In responding to disciplinary problems with a behavior management approach, the best practice is combining punishment-techniques to decrease inappropriate behavior with reinforcement techniques to increase desirable behaviors, while emphasizing use of the latter.

The choice of behavioral strategies and extent of their use obviously would depend on the type and severity of the behavior problem. For mild kinds of inappropriate behavior, Emmer (1987) recommends a four-step strategy, which is consistent with the preventive classroom management model's emphasis on minimal disruption of learning: (a) Look the student in the eye until the behavior stops, (b) move closer to the student, (c) use a nonverbal cue (e.g., a finger to the lips), and (d) state the student's name or ask the student to stop the behavior. Redirecting the students to appropriate behavior also is highly recommended. For more serious classroom misbehaviors (e.g., fighting, verbal abuse, continual noncompliance, property damage) more punitive behavioral strategies such as time-out, response cost, and detention might be used. Emmer recommends that the following principles be considered when using punishment:

1. Whenever possible, the punishment should relate logically to the misbehavior.

2. Severe punishment is frequently no more effective than moderate punishment and at times less so.

3. Punishment procedures should be focused on helping the student understand the problem and make a commitment to change to more acceptable behavior.

4. When punishment is used, it should not be overused, with respect to either time or frequency.

5. Consistency is essential.

An interdependent group contingency technique called the "Good Behavior Game" (Barrish, Saunders, & Wolf, 1969) should be considered when dealing with classes in which several or more children are misbehaving. Like many other behavioral techniques, the "game" also can be used to prevent behavior problems. Different variations of the game have been used, but most share common features: (a) specific classroom rules are listed, (b) the class is divided into two or more "teams," (c) each team receives a mark on the board whenever a member of that team violates a rule, and (d) the team(s) receiving points below a predetermined criterion number are offered reinforcement (extra recess, less homework, other privileges and rewards).

In addition to being simple to use and effective, the Good Behavior Game is liked by teachers. However, school psychologists should be aware of its negative features, including the potential for undue and harmful peer pressure and ridicule of those students who cause their team to lose, and its emphasis on the reduction of inappropriate behavior. Unfortunately, the latter negative feature applies to most other punishment- or control-oriented contingency procedures in which students are not taught prosocial behaviors (see Graham-Clay & Reschly, 1987, for a review of legal and ethical issues). However, many of these problems can be overcome by basing points in the game on the presence of positive behaviors as opposed to the absence of negative behaviors (Darveaux, 1984).

Assertive Discipline. With over 500,000 teachers having been trained in its use, Assertive Discipline (Canter & Canter, 1976) is perhaps the most popular commercially available behavior management program used in the schools. Canter and Canter argue that teachers have the right to maintain classroom order and to obtain assistance in disciplinary matters from parents, principals, and others. In protecting these rights, teachers must be assertive. The best way to assert themselves in the classroom is to correct or control student misbehavior by means of the systematic use of an amalgamation of behavior management techniques. Such techniques include the continuous monitoring of behavior (a mark is put on the board when a child violates a classroom rule), behavioral contracting, response cost, verbal reprimands, sending the student to the principal, and suspending the student from school. Positive "assertions" (privileges, rewards, positive parent contacts, token reinforcement) also are employed, contingent upon the absence of misbehavior.

Each of the behavior management techniques described here, including those used in the Assertive Discipline program, has been shown to effectively increase or decrease behavior, at least on a short-term basis. Behavior management techniques are recognized widely as being a necessary, although not sufficient, component of most comprehensive programs of discipline. That is, although necessary for classroom management, they are not sufficient for teaching self-discipline. As noted earlier, it is important that models of discipline balance the teacher's need for control with the child's need for self-discipline. Programs that focus specifically on teacher control, such as Assertive Discipline, fail to offer such a balance (Render, Padilla, & Krank, 1989). Unless such balance is provided, Assertive Discipline should not be considered a best practice.

Reality Therapy model. Like Assertive Discipline, Reality Therapy (Glasser, 1965, 1969) is a popular school-wide systems model for discipline that uses specific behavior management strategies. However, the model is much more comprehensive, viewing discipline as entailing much more than the management of behavior. Reality Therapy emphasizes the importance of democratic school governance, student values and responsibility, avoidance of student failure, and the use of classroom meetings to develop social problem-solving skills and moral reasoning. As such, it could be considered a preventive model of discipline but is presented here under corrective models because Reality Therapy is one of the few models that offers specific and sequential steps for dealing with actual cases of discipline problems. Glasser provides educators with a practical 10-step procedure for dealing with discipline problems in a fashion which empowers both teachers and students. The ten steps are:

1. Teacher asks "What are you doing?"

2. The student evaluates the misbehavior and makes a commitment to stop it.

3. The teacher plans for student success.

4. When the problem reoccurs, the teacher directs the student to stop the misbehavior.

5. If step #4 is unsuccessful, the teacher questions the student about the misbehavior and describes appropriate behaviors.

6. If step #5 is unsuccessful, the teacher briefly repeats the questions in #5 and firmly tells the student that the misbehavior has to be stopped and a corrective plan developed. The plan is developed by the student and is approved and enforced by the teacher.

7. If misbehavior continues, in-class time-out is used.

8. If misbehavior continues, in-school time-out is used.

9. If misbehavior continues, out-of-school suspension is used. The student is not allowed to return until an acceptable plan has been made.

10. If #9 continues to be unsuccessful, the student is referred for homebound instructions and/or treatment. (Glasser, 1975)

Treatment Models

Students who exhibit a consistent pattern of antisocial behavior, or those who are "at risk" for developing such a pattern, often demand more than what a preventive program or standard disciplinary procedure can provide. At-risk indicators include: (a) poor parental management; (b) early onset of antisocial behavior; (c) reports of stealing, lying, or truancy; (d) antisocial behavior within the family; (e) poor educational achievement; and (f) rejection by peers (Loeber & Dishion, 1983; Parker & Asher, 1987). Presence of a combination of these indicators typically would warrant consideration of the need for a program that is more intensive, broadly based, and lasting than programs reviewed previously.

Treatment programs employ many of the same techniques presented earlier, but their application is more intensive and extensive. Researchers have shown that students with conduct disorders can benefit from programs based on the social problem-solving model (e.g., Kazdin, Esveldt-Dawson, French, & Unis, 1987), the cognitive-developmental model of moral education (e.g., Arbuthnot & Gordon, 1986), the behavior management model (Kazdin, 1982), and combinations of the above (e.g., Aggression Replacement Training, Goldstein & Glick, 1987; *Prepare Curriculum*, Goldstein, 1988). Additional models and techniques available for treating conduct disorders include individual and group psychotherapy, behavior therapy, pharmacotherapy, residential treatments, family therapy, and parent training.

In a comprehensive review of treatments for antisocial behaviors of children and adolescents, Kazdin (1987) concluded that the most promising treatments are parent management training, functional family therapy, cognitive problem-solving skills training (including social problem-solving and cognitive-developmental moral discussion techniques), and community-based treatment. Although behavior therapies such as behavior modification and social skills training were found to control effectively or decrease isolated antisocial behaviors, Kazdin noted that there is very little evidence that their effects are lasting or that the skills learned transfer beyond the training setting and to other domains. Therefore, he recommends broad-based programs in which alternative techniques are combined to address the multiple and complex factors influencing antisocial behavior. Kazdin also warns that these techniques should not be chosen haphazardly but rather on the basis of theoretical and conceptual justifications.

Selecting and Implementing Models and Techniques

It is not enough that school psychologists simply possess knowledge of models and techniques that prevent, correct, and treat discipline problems. They must also possess the process skills necessary to help teachers and parents select and apply such models and techniques. Several models of school-based consultation provide such a process, particularly for helping schools prevent and deal with disciplinary problems. The choice of consultation model, or combination of models, likely is influenced by many factors including the appropriate level of consultation (direct service to student or consultee, or indirect to the consultee or the organization), pervasiveness and nature of the problem, and the training and expected role of the school psychologist. Knoff (1985) suggests that the behavioral consultation model is most appropriate when examining environmental causes of misbehavior and when selecting among behavior modification techniques. The mental health model is used when the teachers are unable to deal effectively with student misbehavior due to lack of knowledge, experience, confidence, or objectivity. It also appears that the systems consultation model (see Curtis this volume) is applicable when assessing, developing, and implementing school-wide preventive policies and programs. When functioning as a member of a child study or intervention team, the school psychologist should find the collaborative consultation model provides useful direction.

Regardless which consultation model is used, sequential problem-solving steps should guide the consultation process. Knoff (1985) and Bear (1990) offered a four-step problem-solving process for dealing with discipline referrals, consisting of problem identification, problem analysis, intervention, and evaluation. A slightly different four-step process is presented next, one that devotes greater attention to the planning of interventions. Whereas the following steps most directly relate to cases of corrective discipline involving the classroom teacher and a child, it should be clear that these same four steps could be applied when developing preventive or treatment programs. The same process would be used, but many of the guiding questions would change. Likewise, the same four-step process could be used when helping children solve disciplinary problems on their own.

Note that the "consultee" referred to while discussing this process likely is the classroom teacher, but depending on the case and level of consultation it might be the student's parent(s), administrator(s), or groups thereof. Given that discipline problems are influenced by multiple and complex forces, best practice involves as many parties as feasible, but almost always the teacher, parent, and child. In keeping with this best practice objective, it is recognized that at times services of the school psychologist must not be restricted by an indirect, consultee-centered service approach. More direct, as well as other indirect services either separate from or combined with consultation, often are called for when dealing with disciplinary problems. This would include individual or group counseling, parent education, and inservice education (see Frisby, 1990, regarding inservice programs on discipline).

Problem identification. The critical first step in the problem-solving process is for the school psychologist and the consultee to pinpoint and define clearly the disciplinary problem(s) that led the consultee to seek assistance. This would require the identification of observable behaviors in concrete behavioral terms, both those that are desired and those that are undesired. Ideally, the school psychologist should observe the child in the setting(s) in which the behavior occurs and have the teacher establish a baseline of the frequency of undesired and desired behaviors.

It is at this step that the consultant should determine, at least tentatively, the severity of the problem(s) and who "owns" the problem(s). Determination of severity and ownership is critical to decisions made at later stages in the process, particularly in selecting the method and intensity of the intervention warranted. Obviously, inappropriate behaviors that are developmentally "normal," such as getting out of one's seat and talking in class, call for different disciplinary methods than the more severe problems such as stealing or unprovoked fighting, particularly when the latter behaviors occur frequently. Likewise, the focus of intervention would differ if the probelm behaviors reflect the teacher's poor classroom management rather than the child's lack of self-discipline.

Problem analysis. During this phase problems tentatively identified during problem identification are now examined in greater depth. Who "owns" the problem becomes clearer upon analysis of environmental factors (including situational antecedents and consequences), and the cognitions and behaviors of the student, consultee, and perhaps others who might be influencing the problem behavior. This analysis would almost always require informal assessments of the student's social problem-solving skills, self-perceptions, moral reasoning, and self-attributions, as well as the skills, expectations, self-confidence, and attributions of the consultee.

An interview with the child (by the school psychologist, consultee, or other member of an intervention team), a review of records, and classroom observations generally should precede the meeting during which problem analysis occurs. Family and peer relations and their impact on discipline also should be explored in recognition of the critical (and reciprocal) role of parental discipline in children's antisocial behavior (Vuchinich, Gank, & Patterson, 1992; Walker, Stieber, Ramsey, & O'Neill, 1991).

Guiding questions at this step include the following:

- Does the primary problem lie in the student not having appropriate prosocial skills and inhibitory controls, or in the student possessing but not exhibiting them?
- To whom, or what, do the student, teacher, and parent attribute the disciplinary problem?
- To what extent are such attributions biased?
- Do the consultee's discipline-related expectations, self-efficacy beliefs, or lack of knowledge contribute to the misbehavior?
- Are current disciplinary practices fair and implemented correctly?
- Do forces beyond the teacher–student relationship impinge upon the behavior (e.g., school climate, peers, parents, etc.)?
- In what ways might the above factors be related reciprocally?

Bandura's (1978) model of reciprocal determinism provides a useful framework for problem analysis because it focuses on the continuous reciprocal interaction between a person's cognitions, behaviors, and environmental factors.

Planning. The ultimate choice of model(s) and techniques rests with the consultee. The school psychologist's primary role, particularly during the collaborative planning phase, is to facilitate the decision-making process and to offer information and advice that might influence the consultee's choice of intervention(s). While brainstorming and evaluating models and/or strategies with the consultee, the school psychologist should advocate for the ones with the greatest potential for solving the immediate problem and for teaching the child self-discipline. Choice of model and/or strategies should be linked to information gleaned from problem identification and problem analysis and to the specific goals of the consultee. Of particular importance is information that indicates the extent and breadth of the intervention needed to bring about changes in behavior that are consistent with the consultee's goals.

Lepper's (1983) "minimal sufficiency principle" provides some guidance for selecting techniques during this phase. According to this principle, the internalization of social and moral norms is fostered by disciplinary procedures that exert the least amount of pressure on a student to conform. If this principle were followed in the classroom, the use of external controls would be minimal and used only when necessary. Some practical support for Lepper's principle comes from studies showing that interventions with a large number of self-management components (as opposed to teacher-management components) yield the greatest effects in curtailing misbehavior (Fantuzzo, Polite, Cook, & Quinn, 1988).

Factors which enhance the likelihood of the intervention being implemented successfully also should be considered. Based on research (see Greenwood, Carta, & Hall, 1987; Gresham, 1991) on the effectiveness and acceptability of interventions the following questions should be addressed:

- Has previous research shown the intervention to be effective under similar classroom conditions?
- Is the intervention sufficiently comprehensive and systematic?
- Are procedures clear and likely to be followed by the interventionist(s)?
- Are attempts made to involve the student in planning and implementation of the intervention?
- Are parents involved?
- Is the intervention acceptable to the teacher, parent, principal, and student?

Negative answers to these questions are likely to suggest difficulties and perhaps failure.

Teachers prefer interventions that are positive, of brief duration, and easy and inexpensive to implement, but recognize that more serious offenses require aversive and longer-lasting interventions (see Reimers, Wacker, & Koeppl, 1987). A recent survey (King, Gullone, & Dadds, 1990) of over 3,000 teachers in Great Britain found that reasoning with the individual student was the strategy of choice in dealing with run-of-the-mill disciplinary problems. A smaller scaled study by Rosen, Taylor, O'Leary, and Sanderson (1990) of teachers in the United States also found verbal management techniques to be most preferred. In addition to reasoning with the individual student, two additional easy-to-use and effective interventions preferred by teachers were redirecting students toward appropriate behavior and manipulating rewards (Martens, Peterson, Witt, & Cirone, 1986).

Whereas the teacher's acceptance of an intervention is important for obvious reasons, the importance of the student's acceptance is less clear. Group questionnaires show that most students accept discipline techniques that traditionally have been used by teachers, such as teacher–student discussion, time-out, and sending the misbehaving child to the principal (Bear & Stewart, 1990; King, Gullone, & Dadds, 1990), but dislike class-wide discussion or meetings with a school counselor (Bear & Stewart, 1990). Private reprimands are preferred over public ones and whole-class interventions clearly are disliked when imposed for the misbehavior of a few class members (Lovegrove, Lewis, Fall, & Lovegrove, 1985). Studies also show that in evaluating the fairness and perceived effectiveness of interventions students consider behavior problem severity as well as transgressor's reputation (Bear & Fink, 1991). That is, they recognize that harsh measures are fair (although not necessarily effective) for repeated violators of moral transgressions but are unfair for those who rarely misbehave, particularly if the misbehavior is minor.

A problem with group studies of student acceptability, however, is that the results may not apply to individuals with whom the techniques are used. A best practice with respect to student acceptance is to implement interventions viewed most favorably by the student. This is especially true when dealing with adolescents. However, one should not let the consideration of the student's acceptance preclude implementation of an intervention that is acceptable to all others, fair, and likely to be effective.

Implementation and evaluation. The effectiveness of any discipline program largely is dependent on the manner in which it is implemented. Even the most well-planned and best designed interventions likely will be ineffective when they are poorly implemented. In addition to addressing and resolving implementation-related concerns during the planning phase, adhering to certain practices during actual implementation likely will enhance program effectiveness. Four such practices (adapted from Weissberg, Caplan, & Sivo, 1989) are: (a) Develop a structured and detailed curriculum for preventive programs and provide specific procedures for dealing with misbehavior; (b) offer individual- or school-wide teacher training before and during the program; (c) provide classroom assistance, supervision, and on-site coaching, when needed; and (d) organize system policies and supports that encourage program integrity.

In evaluating discipline programs, there are many evaulation models and designs from which to choose. Likewise, there is a multitude of instruments for measuring the objectives of most models (e.g., measures of classroom management, self-concept, values, attitudes, moral reasoning, self-efficacy, antisocial behavior). The matching of program objectives with evaluation measures is of critical importance. Many local intervention programs have been "ineffective" due to the use of instruments (e.g., self-esteem inventories) that indirectly measure, or fail to measure, intended outcomes.

The complexity of the evaluation design largely depends on the purpose of the evaluation and the level at which consultation services are provided. Whereas sophisticated experimental and quasi-experimental group research designs are necessary for most system-level projects, simpler case study designs are appropriate when the focus is on an individual student or a small group of students. Regardless of the level of complexity, however, both the process of planning and decision-making (i.e., formative evaluation) and the outcomes of interventions (i.e., summative evaluation) should be evaluated. "If" and "how" an intervention succeeds or fails are equally important (Scriven, 1967). Likewise, evaluation should be ongoing so that interventions can be revised when necessary. Evaluation also should include both objective and subjective data, examine intended and unintended effects, and allow for a follow-up period (Brown, Pryzwansky, & Schulte, 1987; Knoff, 1982). Moreover, in order to promote self-management the student should be included in the evaluation process.

SUMMARY

Responding to discipline problems requires knowledge and skills in many areas, especially child development, behavior management, classroom effectiveness, and consultation. To be effective, school-based discipline programs must be broad-based, incorporating a variety of techniques designed to prevent, correct, and treat varying degrees of misbehavior.

The ultimate goal of a discipline program should be the development of self-directed behavior that is socially and morally responsible. To achieve this goal, programs must focus not only on improving the abilities of significant others to prevent and deal with discipline problems, but also on developing the cognitions, affect, and behaviors among children that might prevent discipline problems.
